

## LLM: Qwen 2.5 Coder (32B parameter version)

>>> **Using Python, pyarrow, and pandas, write: A function that searches a specified directory for .parquet files and CSV files, and places their file paths into separate lists. Next, write: a function that opens one .parquet file at a time, read it into a pandas dataframe, change the name of each column, then write the modified data into a new file.**

Certainly! Below is the Python code that accomplishes the tasks you've described:

1. A function to search a specified directory for `.parquet` and `.CSV` files, placing their file paths into separate lists.
2. A function to open one `.parquet` file at a time, read it into a pandas DataFrame, rename its columns, and write the modified data into a new file.

First, make sure you have the necessary libraries installed:

```
```bash
pip install pyarrow pandas
```
```

Here is the complete code:

```
```python
import os
import pandas as pd

def list_files_in_directory(directory):
    """
    Search for .parquet and CSV files in the specified directory.

    Args:
        directory (str): The path to the directory to search.

    Returns:
        tuple: Two lists, one with .parquet file paths and one with CSV
        file paths.
    """
    parquet_files = []
    csv_files = []

    for root, _, files in os.walk(directory):
        for file in files:
            if file.endswith('.parquet'):
                parquet_files.append(os.path.join(root, file))
            elif file.endswith('.csv'):
                csv_files.append(os.path.join(root, file))

    return parquet_files, csv_files
```
```

```

def process_parquet_file(parquet_path, output_directory):
    """
    Read a .parquet file into a pandas DataFrame, rename its columns,
    and write the modified data to a new .parquet file.

    Args:
        parquet_path (str): The path to the input .parquet file.
        output_directory (str): The directory where the modified .parquet
        file will be saved.

    Returns:
        str: The path to the newly created .parquet file with modified
        columns.
    """
    # Read the .parquet file
    df = pd.read_parquet(parquet_path)

    # Rename the columns (example renaming, adjust as needed)
    new_column_names = {col: f"new_{col}" for col in df.columns}
    df.rename(columns=new_column_names, inplace=True)

    # Define the output path
    file_name = os.path.basename(parquet_path).replace('.parquet',
'_modified.parquet')
    output_path = os.path.join(output_directory, file_name)

    # Write the modified DataFrame to a new .parquet file
    df.to_parquet(output_path)

    return output_path

# Example usage:
if __name__ == "__main__":
    directory_to_search = '/path/to/your/directory'
    parquet_files, csv_files =
list_files_in_directory(directory_to_search)

    print("Parquet files found:")
    for file in parquet_files:
        print(file)

    print("\nCSV files found:")
    for file in csv_files:
        print(file)

    # Process each .parquet file

```

```

output_dir = '/path/to/output/directory'
if not os.path.exists(output_dir):
    os.makedirs(output_dir)

for parquet_file in parquet_files:
    new_file_path = process_parquet_file(parquet_file, output_dir)
    print(f"Processed {parquet_file} and saved as {new_file_path}")
...

```

### ### Explanation:

1. **`**list_files_in_directory(directory):**`**
  - This function searches the given directory for `.parquet` and `CSV` files using `os.walk`.
  - It collects file paths in two separate lists: one for `.parquet` files and another for CSV files.
2. **`**process_parquet_file(parquet_path, output_directory):**`**
  - This function reads a specified `.parquet` file into a pandas DataFrame.
  - It renames all columns by prepending `'new_'` to the original column names (you can modify this renaming logic as needed).
  - The modified DataFrame is then written to a new `.parquet` file in the specified output directory.

### ### Example Usage:

- Replace ``/path/to/your/directory`` with the path of the directory you want to search.
- Replace ``/path/to/output/directory`` with the path where you want to save the modified `.parquet` files.
- The script will print out all found `.parquet` and CSV files, and then process each `.parquet` file by renaming its columns and saving the result in the specified output directory.

~~~~~

**>>> Next, using Python, pandas, and pyarrow, write: a function that opens one c  
 ... sv file from the list at a time, reads it one line at a time into a pandas d  
 ... atafame (ignoring csv headers if present), adding a name to each column in  
 ... the dataframe. Next, the dataframe will be written to a .parquet file. Conti  
 ... nue writing to the same parquet file until it's file size is approximately 1  
 ... 28 MiB, and then create a new .parquet file. Use Path.stat() to track the fi  
 ... le size.**

Certainly! Below is the Python code that accomplishes the tasks you've described:

1. A function to read one CSV file from the list at a time, reading it line by line into a pandas DataFrame while ignoring the CSV headers.

2. Adding a name to each column in the DataFrame.
3. Writing the DataFrame to a `.parquet` file until its size is approximately 128 MiB, and then creating a new `.parquet` file.

Here's the complete code:

```
```python
import os
import pandas as pd
from pyarrow import parquet as pq
from pathlib import Path

def list_files_in_directory(directory):
    """
    Search for .parquet and CSV files in the specified directory.

    Args:
        directory (str): The path to the directory to search.

    Returns:
        tuple: Two lists, one with .parquet file paths and one with CSV
    file paths.
    """
    parquet_files = []
    csv_files = []

    for root, _, files in os.walk(directory):
        for file in files:
            if file.endswith('.parquet'):
                parquet_files.append(os.path.join(root, file))
            elif file.endswith('.csv'):
                csv_files.append(os.path.join(root, file))

    return parquet_files, csv_files

def process_csv_to_parquet(csv_path, output_directory):
    """
    Read a CSV file line by line into a pandas DataFrame, ignore headers,
    add column names, and write the DataFrame to .parquet files in chunks
    of approximately 128 MiB.

    Args:
        csv_path (str): The path to the input CSV file.
        output_directory (str): The directory where the .parquet files
    will be saved.

    Returns:
        list: List of paths to the created .parquet files.
    """
```

```

"""
# Define column names
column_names = [f"column_{i}" for i in range(10)] # Adjust the number
of columns as needed

# Initialize variables
chunk_size = 10000 # Number of rows to read at a time
parquet_files = []

df = pd.concat(current_chunk)

# Define output path if not set or if file size exceeds 128 MiB
if current_parquet_path is None:
    file_counter += 1
    current_parquet_path = os.path.join(output_directory,
f"output_{file_counter}.parquet")
    parquet_files.append(current_parquet_path)

# Write DataFrame to .parquet file
df.to_parquet(current_parquet_path, index=False, engine='pyarrow',
mode='a')

# Check the size of the current .parquet file
if Path(current_parquet_path).stat().st_size >= 128 * 1024 * 1024:
# 128 MiB
    current_chunk = []
    current_parquet_path = None

return parquet_files

# Example usage:
if __name__ == "__main__":
    directory_to_search = '/path/to/your/directory'
    parquet_files, csv_files =
list_files_in_directory(directory_to_search)

```

```

print("Parquet files found:")
for file in parquet_files:
    print(file)

print("\nCSV files found:")
for file in csv_files:
    print(file)

# Process each CSV file
output_dir = '/path/to/output/directory'
if not os.path.exists(output_dir):
    os.makedirs(output_dir)

for csv_file in csv_files:
    new_parquet_files = process_csv_to_parquet(csv_file, output_dir)
    print(f"Processed {csv_file} and created the following .parquet
files:")
    for parquet_file in new_parquet_files:
        print(parquet_file)
...

```

### ### Explanation:

1. **\*\*list\_files\_in\_directory(directory):\*\***
  - This function searches the given directory for `.parquet`` and `CSV`` files using `os.walk``.
  - It collects file paths in two separate lists: one for `.parquet`` files and another for CSV files.
2. **\*\*process\_csv\_to\_parquet(csv\_path, output\_directory):\*\***
  - This function reads a specified CSV file line by line into a pandas DataFrame while ignoring the CSV headers.
  - It assigns default column names (e.g., `column_0``, `column_1``, etc.). You can adjust the number of columns as needed.
  - The DataFrame is built in chunks, and each chunk is written to a `.parquet`` file.
  - The function checks the size of the current `.parquet`` file using `Path.stat().st_size``.
  - If the file size exceeds 128 MiB, it starts writing to a new `.parquet`` file.

### ### Example Usage:

- Replace `"/path/to/your/directory"` with the path of the directory you want to search.
- Replace `"/path/to/output/directory"` with the path where you want to save the created `.parquet`` files.
- The script will print out all found `.parquet`` and CSV files, and then process each CSV file by reading it line by line, renaming its columns,

and saving the result in chunks of approximately 128 MiB into separate  
`.parquet` files.

~~~~~

>>> **The script you wrote is constantly overwriting the same file, rather than letting it grow to approx 128 MiB and creating a new parquet file to write to.**

...  
You're correct that the current implementation is overwriting the same file instead of allowing it to grow to approximately 128 MiB before creating a new one. Let's address this by ensuring that each chunk is appended correctly to the existing `.parquet` file until it reaches the desired size, and then a new file is created.

Here's the corrected version of the script:

```
```python
import os
import pandas as pd
from pyarrow import parquet as pq
from pathlib import Path

def list_files_in_directory(directory):
    """
    Search for .parquet and CSV files in the specified directory.

    Args:
        directory (str): The path to the directory to search.

    Returns:
        tuple: Two lists, one with .parquet file paths and one with CSV
        file paths.
    """
    parquet_files = []
    csv_files = []

    for root, _, files in os.walk(directory):
        for file in files:
            if file.endswith('.parquet'):
                parquet_files.append(os.path.join(root, file))
            elif file.endswith('.csv'):
                csv_files.append(os.path.join(root, file))

    return parquet_files, csv_files

def process_csv_to_parquet(csv_path, output_directory):
    """
```

Read a CSV file line by line into a pandas DataFrame, ignore headers, add column names, and write the DataFrame to .parquet files in chunks of approximately 128 MiB.

Args:

csv\_path (str): The path to the input CSV file.

output\_directory (str): The directory where the .parquet files will be saved.

Returns:

list: List of paths to the created .parquet files.

"""

# Define column names

column\_names = [f"column\_{i}" for i in range(10)] # Adjust the number of columns as needed

# Initialize variables

chunk\_size = 10000 # Number of rows to read at a time

parquet\_files = []

current\_parquet\_path = None

file\_counter = 0

# Ensure output directory exists

if not os.path.exists(output\_directory):

os.makedirs(output\_directory)

# Read the CSV file line by line

for chunk in pd.read\_csv(csv\_path, header=None, names=column\_names, chunksize=chunk\_size):

# Define output path if not set or if file size exceeds 128 MiB

if current\_parquet\_path is None:

file\_counter += 1

current\_parquet\_path = os.path.join(output\_directory, f"output\_{file\_counter}.parquet")

parquet\_files.append(current\_parquet\_path)

# Write DataFrame to .parquet file in append mode if it already exists

write\_mode = 'a' if Path(current\_parquet\_path).exists() else 'w'

chunk.to\_parquet(current\_parquet\_path, index=False, engine='pyarrow', mode=write\_mode)

# Check the size of the current .parquet file

if Path(current\_parquet\_path).stat().st\_size >= 128 \* 1024 \* 1024: # 128 MiB

current\_parquet\_path = None

return parquet\_files

# Example usage:

if \_\_name\_\_ == "\_\_main\_\_":

directory\_to\_search = '/path/to/your/directory'

parquet\_files, csv\_files =

list\_files\_in\_directory(directory\_to\_search)

```

print("Parquet files found:")
for file in parquet_files:
    print(file)

print("\nCSV files found:")

        print(parquet_file)
...

```

### ### Explanation:

1. **`**list_files_in_directory(directory):**`**
  - This function searches the given directory for ``.parquet`` and ``.CSV`` files using ``.os.walk``.
  - It collects file paths in two separate lists: one for ``.parquet`` files and another for CSV files.
2. **`**process_csv_to_parquet(csv_path, output_directory):**`**
  - This function reads a specified CSV file line by line into a pandas DataFrame while ignoring the CSV headers.
  - It assigns default column names (e.g., ``.column_0``, ``.column_1``, etc.). You can adjust the number of columns as needed.
  - The DataFrame is built in chunks, and each chunk is written to a ``.parquet`` file.
  - The function checks the size of the current ``.parquet`` file using ``.Path.stat().st_size``.
  - If the file size exceeds 128 MiB, it sets ``.current_parquet_path`` to ``.None``, which will trigger the creation of a new ``.parquet`` file in the next iteration.
  - The ``.mode='a'`` parameter ensures that chunks are appended to the existing file, while ``.mode='w'`` is used for writing a new file.

### ### Example Usage:

- Replace ``.path/to/your/directory`` with the path of the directory you want to search.
- Replace ``.path/to/output/directory`` with the path where you want to

save the created `.parquet` files.

- The script will print out all found `.parquet` and CSV files, and then process each CSV file by reading it line by line, renaming its columns, and saving the result in chunks of approximately 128 MiB into separate `.parquet` files.

~~~~~  
**>>> Use pyarrow to write to .parquet files, not pandas**

Certainly! To ensure that we use `pyarrow` for writing to `.parquet` files, we need to make some adjustments to the code. Specifically, we'll use `pyarrow.Table` and `pyarrow.parquet.write\_table` to handle the writing process.

Here's the updated script:

```
```python
import os
import pandas as pd
import pyarrow as pa
from pyarrow import parquet as pq
from pathlib import Path

def list_files_in_directory(directory):
    """
    Search for .parquet and CSV files in the specified directory.

    Args:
        directory (str): The path to the directory to search.

    Returns:
        tuple: Two lists, one with .parquet file paths and one with CSV
    file paths.
    """
    parquet_files = []
    csv_files = []

    for root, _, files in os.walk(directory):
        for file in files:
            if file.endswith('.parquet'):
                parquet_files.append(os.path.join(root, file))
            elif file.endswith('.csv'):
                csv_files.append(os.path.join(root, file))

    return parquet_files, csv_files

def process_csv_to_parquet(csv_path, output_directory):
    """
    Read a CSV file line by line into a pandas DataFrame, ignore headers,
```

add column names, and write the DataFrame to .parquet files in chunks of approximately 128 MiB.

Args:

csv\_path (str): The path to the input CSV file.

output\_directory (str): The directory where the .parquet files will be saved.

Returns:

list: List of paths to the created .parquet files.

"""

# Define column names

column\_names = [f"column\_{i}" for i in range(10)] # Adjust the number of columns as needed

# Initialize variables

chunk\_size = 10000 # Number of rows to read at a time

parquet\_files = []

current\_parquet\_path = None

file\_counter = 0

# Ensure output directory exists

if not os.path.exists(output\_directory):

os.makedirs(output\_directory)

# Read the CSV file line by line

for chunk in pd.read\_csv(csv\_path, header=None, names=column\_names, chunksize=chunk\_size):

# Convert DataFrame to pyarrow Table

table = pa.Table.from\_pandas(chunk)

# Define output path if not set or if file size exceeds 128 MiB

if current\_parquet\_path is None:

file\_counter += 1

current\_parquet\_path = os.path.join(output\_directory, f"output\_{file\_counter}.parquet")

parquet\_files.append(current\_parquet\_path)

# Write Table to .parquet file in append mode if it already exists

write\_mode = 'a' if Path(current\_parquet\_path).exists() else 'wb'

pq.write\_table(table, current\_parquet\_path, compression='snappy', mode=write\_mode)

# Check the size of the current .parquet file

if Path(current\_parquet\_path).stat().st\_size >= 128 \* 1024 \* 1024: # 128 MiB

current\_parquet\_path = None

return parquet\_files

# Example usage:

if \_\_name\_\_ == "\_\_main\_\_":

directory\_to\_search = '/path/to/your/directory'

parquet\_files, csv\_files =

list\_files\_in\_directory(directory\_to\_search)

```

print("Parquet files found:")
for file in parquet_files:
    print(file)

print("\nCSV files found:")
for file in csv_files:
    print(file)

# Process each CSV file
output_dir = '/path/to/output/directory'
if not os.path.exists(output_dir):
    os.makedirs(output_dir)

for csv_file in csv_files:
    new_parquet_files = process_csv_to_parquet(csv_file, output_dir)
    print(f"Processed {csv_file} and created the following .parquet files:")
    for parquet_file in new_parquet_files:
        print(parquet_file)
...

```

#### ### Explanation:

1. **`**list_files_in_directory(directory):**`**
  - This function searches the given directory for ``.parquet`` and ``.CSV`` files using ``.os.walk``.
  - It collects file paths in two separate lists: one for ``.parquet`` files and another for CSV files.
2. **`**process_csv_to_parquet(csv_path, output_directory):**`**
  - This function reads a specified CSV file line by line into a pandas DataFrame while ignoring the CSV headers.
  - It assigns default column names (e.g., ``.column_0``, ``.column_1``, etc.). You can adjust the number of columns as needed.
  - The DataFrame is converted to a ``.pyarrow.Table`` using ``.pa.Table.from_pandas(chunk)``.
  - The function writes the ``.pyarrow.Table`` to a ``.parquet`` file using ``.pq.write_table``.
  - The ``.mode='a'`` parameter ensures that tables are appended to the existing file, while ``.mode='wb'`` is used for writing a new file.
  - The function checks the size of the current ``.parquet`` file using ``.Path.stat().st_size``.
  - If the file size exceeds 128 MiB, it sets ``.current_parquet_path`` to ``.None``, which will trigger the creation of a new ``.parquet`` file in the next iteration.

#### ### Example Usage:

- Replace ``.path/to/your/directory`` with the path of the directory you want to search.

- Replace ``/path/to/output/directory`` with the path where you want to save the created ``.parquet`` files.
- The script will print out all found ``.parquet`` and CSV files, and then process each CSV file by reading it line by line, renaming its columns, and saving the result in chunks of approximately 128 MiB into separate ``.parquet`` files using ``.pyarrow``.

## ~~~~~

### Using python, what are the best ways to preprocess financial tick-data for machine learning that are both fast (multiprocessed, ideally) and efficient (in terms of RAM usage)?

Preprocessing financial tick data efficiently while ensuring speed and low memory usage can be challenging due to the high volume and frequency of such data. Here's a structured approach using Python with libraries like ``.pandas``, ``.numpy``, ``.dask``, and ``.multiprocessing``:

#### ### 1. **Use Efficient Data Structures**

- **Pandas**: For moderate-sized datasets, ``.pandas`` provides powerful tools for time series manipulation.
- **Dask**: Ideal for larger-than-memory computations as it parallelizes operations over multiple cores.

#### ### 2. **Multiprocessing and Parallelization**

- **Multiprocessing**: Use Python's built-in ``.multiprocessing`` module to split data processing across multiple CPU cores.
- **Joblib or Dask**: These libraries offer higher-level abstractions for parallel execution, which can be more convenient than raw multiprocessing.

#### ### 3. **Optimize Data Types**

- Convert data types to reduce memory usage (``.float64`` to ``.float32``, ``.int64`` to ``.int32`` when possible).
- Use categorical data types where applicable (e.g., for ``.symbol`` or ``.exchange``).

#### ### 4. **Chunk Processing**

- Process data in chunks rather than loading the entire dataset into memory.

#### ### Example Workflow

Here's a sample code using these principles:

#### #### Using Pandas and Multiprocessing

```
```python
import pandas as pd
import numpy as np
from multiprocessing import Pool
from datetime import datetime

# Function to preprocess chunk of data
def preprocess_chunk(chunk):
    # Optimize data types
```

```

chunk['price'] = chunk['price'].astype('float32')
chunk['volume'] = chunk['volume'].astype('int32')

# Add additional features, e.g., time-based features
chunk['timestamp'] = pd.to_datetime(chunk['timestamp'])
chunk['hour'] = chunk['timestamp'].dt.hour.astype('uint8')
chunk['day_of_week'] = chunk['timestamp'].dt.dayofweek.astype('uint8')

return chunk

# Load data in chunks and process them
def preprocess_data(file_path, n_partitions):
    # Read the file in chunks
    reader = pd.read_csv(file_path, chunksize=100_000)

    # Create a pool of processes
    with Pool(processes=n_partitions) as pool:
        processed_chunks = pool.map(preprocess_chunk, reader)

    # Concatenate all chunks into a single DataFrame
    return pd.concat(processed_chunks)

# Example usage
if __name__ == "__main__":
    file_path = 'financial_tick_data.csv'
    n_partitions = 4 # Number of CPU cores or partitions

    start_time = datetime.now()
    df = preprocess_data(file_path, n_partitions)
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")
...

#### Using Dask
```python
import dask.dataframe as dd
from datetime import datetime

# Function to add time-based features
def add_features(df):
    df['timestamp'] = dd.to_datetime(df['timestamp'])
    df['hour'] = df['timestamp'].dt.hour.astype('uint8')
    df['day_of_week'] = df['timestamp'].dt.dayofweek.astype('uint8')
    return df

# Load data using Dask
def preprocess_data_dask(file_path):
    # Read the file as a Dask DataFrame

```

```

ddf = dd.read_csv(file_path)

# Optimize data types
ddf = ddf.assign(price=ddf.price.astype('float32'), volume=ddf.volume.astype('int32'))

# Add additional features
ddf = add_features(ddf)

# Compute the result (this triggers the actual computation)
return ddf.compute()

# Example usage
if __name__ == "__main__":
    file_path = 'financial_tick_data.csv'

    start_time = datetime.now()
    df_dask = preprocess_data_dask(file_path)
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")
'''

#### Considerations
- **Parallel I/O**: Ensure your disk can handle multiple parallel reads/writes efficiently.
- **Memory Management**: Monitor memory usage and adjust chunk sizes as necessary to prevent excessive RAM consumption.

```

By combining these techniques, you can preprocess financial tick data effectively, balancing speed and memory efficiency.

**Leveraging this information, Write a python script that preprocesses financial tick-data stored in a MySQL database. Use "pymysql" to connect to the database. Use "pandas" and not "dask". Get the first and last value in the "trade\_id" column and use them to fetch data from that range; don't use the "OFFSET" keyword. Use "MinMaxScaler" to normalize data from the "price" and "volume" columns to a value between 0 and 1; the "side" column does not need to be normalized. Once each worker is finished with processing a chunk of data, write it to disk. Do not overwrite existing files; append data onto them. Perform this process on 60% of the data and designate it as training data. Then, perform this process on the remaining 40% of the data and designate it as testing data. Finally, merge all of the separate files written to by the workers into 1 file each for training and testing data.**

Certainly! Below is a Python script that preprocesses financial tick-data stored in a MySQL database using `pymysql` for database connection and `pandas` for data manipulation. The script fetches data in chunks, normalizes the `price` and `volume` columns using `MinMaxScaler`, writes the processed chunks to disk, and finally merges them into separate files for training and testing datasets.

```

#### Prerequisites
- Ensure you have the necessary libraries installed:
  ``bash

```

```
pip install pymysql pandas scikit-learn
```
```

```

```

### ### Explanation

1. **\*\*Database Connection\*\***:
  - The ``get_db_connection`` function establishes a connection to the MySQL database using the provided configuration.
2. **\*\*Trade ID Range\*\***:
  - The ``get_trade_id_range`` function retrieves the minimum and maximum trade IDs from the ``tick_data`` table.
3. **\*\*Chunk Fetching\*\***:

- The `fetch_chunk` function fetches data in chunks based on the trade ID range without using the `OFFSET` keyword, which can be inefficient for large datasets.

4. **Data Preprocessing**:

- The `preprocess_chunk` function optimizes data types, adds time-based features, and normalizes `price` and `volume` columns using `MinMaxScaler`.

5. **Writing to CSV**:

- The `write_to_csv` function appends the processed chunk to the specified file path, creating the file if it doesn't exist.

6. **Parallel Processing**:

- The `process_data_in_chunks` function processes data in parallel using a pool of worker processes.
- The main function orchestrates the preprocessing by dividing the data into 60% for training and 40% for testing, then processes each dataset in parallel.

7. **Execution**:

- The script is executed within the `if __name__ == "__main__":` block to ensure that multiprocessing works correctly on Windows systems.

By following this approach, you can efficiently preprocess large financial tick-data stored in a MySQL database using Python, ensuring both speed and memory efficiency.

**So I've modified the script on my own to suit my purposes which I'll show below. What I want you to do is, instead of having the training/testing data be written to CSV files, instead write it to Parquet files.**

```
```python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# File paths for training and testing data
TRAINING_FILE_PATH = 'training_data.csv'
TESTING_FILE_PATH = 'testing_data.csv'

# Function to connect to the MySQL database
def get_db_connection():
    return pymysql.connect(**DB_CONFIG)
```

```

# Function to fetch min and max trade_id from the database
def get_trade_id_range():
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = "SELECT MIN(trade_id), MAX(trade_id) FROM TICK_DATA"
            cursor.execute(query)
            result = cursor.fetchone()
            return result[0], result[1]
    finally:
        connection.close()

```

```

# Function to fetch data in chunks based on trade_id range
def fetch_chunk(start_trade_id, end_trade_id, chunk_size):
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = f"""
                SELECT price, volume, side
                FROM TICK_DATA
                WHERE trade_id BETWEEN {start_trade_id} AND {end_trade_id}
                LIMIT {chunk_size}
            """
            cursor.execute(query)
            columns = [desc[0] for desc in cursor.description]
            data = cursor.fetchall()
            return pd.DataFrame(data, columns=columns)
    finally:
        connection.close()

```

```

# Function to preprocess a chunk of data
def preprocess_chunk(chunk):
    # Optimize data types
    chunk['price'] = chunk['price'].astype('float32')
    chunk['volume'] = chunk['volume'].astype('int32')
    chunk['side'] = chunk['side'].astype('uint8')

    # Add time-based features
    chunk['timestamp'] = pd.to_datetime(chunk['timestamp'])
    chunk['hour'] = chunk['timestamp'].dt.hour.astype('uint8')
    chunk['day_of_week'] = chunk['timestamp'].dt.dayofweek.astype('uint8')

    # Normalize price and volume using MinMaxScaler
    scaler = MinMaxScaler()
    chunk[['price', 'volume']] = scaler.fit_transform(chunk[['price', 'volume']])

    return chunk

```

```

# Function to write a DataFrame to CSV file, appending if it exists
def write_to_csv(df, file_path):
    mode = 'a' if os.path.exists(file_path) else 'w'
    header = not os.path.exists(file_path)
    df.to_csv(file_path, index=False, mode=mode, header=header)

        next_trade_id = min(current_trade_id + chunk_size, end_trade_id)
        chunk = fetch_chunk(current_trade_id, next_trade_id, chunk_size)

        if not chunk.empty:
            processed_chunk = preprocess_chunk(chunk)

            if is_training:
                write_to_csv(processed_chunk, TRAINING_FILE_PATH)
            else:
                write_to_csv(processed_chunk, TESTING_FILE_PATH)

        current_trade_id = next_trade_id

# Main function to orchestrate the preprocessing
def main():
    # Get trade_id range
    start_trade_id, end_trade_id = get_trade_id_range()

    # Calculate 60% and 40% of the data range
    total_range = end_trade_id - start_trade_id + 1
    training_end_trade_id = start_trade_id + int(0.6 * total_range) - 1

    # Define chunk size
    chunk_size = 10_000

    # Number of processes (CPU cores)
    n_partitions = 8 #cpu_count()

    # Prepare arguments for the multiprocessing pool
    args_training = [(start_trade_id, training_end_trade_id, chunk_size, True) for _ in
range(n_partitions)]
    args_testing = [(training_end_trade_id + 1, end_trade_id, chunk_size, False) for _ in
range(n_partitions)]

    # Process training data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_training)

    # Process testing data

```

```

with Pool(processes=n_partitions) as pool:
    pool.starmap(process_data_in_chunks, args_testing)

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")

```

Sure! To modify your script to write the processed data to Parquet files instead of CSV files, you can follow these steps:

1. Change the file paths from `.csv` to `.parquet`.
2. Update the `write\_to\_csv` function to use `to\_parquet` for writing to Parquet format.
3. Ensure that each worker writes to a unique Parquet file to avoid conflicts.

Here's the modified script with these changes:

```

```python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection():
    return pymysql.connect(**DB_CONFIG)

# Function to fetch min and max trade_id from the database
def get_trade_id_range():

```

```

connection = get_db_connection()
try:
    with connection.cursor() as cursor:
        query = "SELECT MIN(trade_id), MAX(trade_id) FROM TICK_DATA"
        cursor.execute(query)
        result = cursor.fetchone()
        return result[0], result[1]
finally:
    connection.close()

# Function to fetch data in chunks based on trade_id range
def fetch_chunk(start_trade_id, end_trade_id, chunk_size):
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = f"""
                SELECT price, volume, side
                FROM TICK_DATA
                WHERE trade_id BETWEEN {start_trade_id} AND {end_trade_id}
                LIMIT {chunk_size}
            """
            cursor.execute(query)
            columns = [desc[0] for desc in cursor.description]
            data = cursor.fetchall()
            return pd.DataFrame(data, columns=columns)
    finally:
        connection.close()

# Function to preprocess a chunk of data
def preprocess_chunk(chunk):
    # Optimize data types
    chunk['price'] = chunk['price'].astype('float32')
    chunk['volume'] = chunk['volume'].astype('int32')
    chunk['side'] = chunk['side'].astype('uint8')

    # Normalize price and volume using MinMaxScaler
    scaler = MinMaxScaler()
    chunk[['price', 'volume']] = scaler.fit_transform(chunk[['price', 'volume']])

    return chunk

# Function to write a DataFrame to Parquet file, appending if it exists
def write_to_parquet(df, file_path):
    df.to_parquet(file_path, index=False)

# Function to process data in chunks and write to disk
def process_data_in_chunks(start_trade_id, end_trade_id, chunk_size, is_training, worker_id):
    current_trade_id = start_trade_id
    while current_trade_id < end_trade_id:

```

```

next_trade_id = min(current_trade_id + chunk_size, end_trade_id)

    if is_training:
        file_path = os.path.join(TRAINING_DIR_PATH,
f'training_worker_{worker_id}_{current_trade_id}.parquet')
    else:
        file_path = os.path.join(TESTING_DIR_PATH,
f'testing_worker_{worker_id}_{current_trade_id}.parquet')

    write_to_parquet(processed_chunk, file_path)

    current_trade_id = next_trade_id

# Function to merge parquet files in a directory into a single DataFrame
def merge_parquet_files(directory):
    return pd.concat([pd.read_parquet(os.path.join(directory, f)) for f in os.listdir(directory) if
f.endswith('.parquet')], ignore_index=True)

# Main function to orchestrate the preprocessing
def main():
    # Get trade_id range
    start_trade_id, end_trade_id = get_trade_id_range()

    # Calculate 60% and 40% of the data range
    total_range = end_trade_id - start_trade_id + 1
    training_end_trade_id = start_trade_id + int(0.6 * total_range) - 1

    # Define chunk size
    chunk_size = 10_000

    # Number of processes (CPU cores)
    n_partitions = 8 # cpu_count()

    # Prepare arguments for the multiprocessing pool
    args_training = [(start_trade_id, training_end_trade_id, chunk_size, True, i) for i in
range(n_partitions)]
    args_testing = [(training_end_trade_id + 1, end_trade_id, chunk_size, False, i) for i in
range(n_partitions)]

    # Process training data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_training)

    # Process testing data

```

```

with Pool(processes=n_partitions) as pool:
    pool.starmap(process_data_in_chunks, args_testing)

# Merge all parquet files into a single DataFrame and write to final file
training_df = merge_parquet_files(TRAINING_DIR_PATH)
testing_df = merge_parquet_files(TESTING_DIR_PATH)

training_df.to_parquet('final_training_data.parquet', index=False)
testing_df.to_parquet('final_testing_data.parquet', index=False)

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")
'''

### Key Changes
1. **Directory Paths**:
    - Changed the file paths to directory paths for training and testing data.

2. **Write to Parquet**:
    - Updated `write_to_parquet` function to use `df.to_parquet(file_path, index=False)`.

3. **Unique File Names**:
    - Added a unique worker ID and trade ID to the file names to avoid conflicts when writing parquet files in parallel.

4. **Merge Parquet Files**:
    - Added `merge_parquet_files` function to merge all parquet files in a directory into a single DataFrame.
    - Wrote the merged DataFrames to final parquet files (`final_training_data.parquet` and `final_testing_data.parquet`).

```

This script ensures that each worker writes to a unique Parquet file, avoiding conflicts, and then merges these files into a single final file for both training and testing datasets.

**Modify the script to ensure that "fetch\_chunk" retrieves the "trade\_id" column as well, and to ensure that each worker doesn't have it's work overlap with another worker.**

Certainly! To ensure that each worker processes a unique range of `trade\_id` values without overlap, we need to carefully distribute the `trade\_id` ranges among the workers. Here's how you can modify the script:

1. **Fetch `trade\_id` along with other columns**: Modify the `fetch\_chunk` function to include the `trade\_id` column.
2. **Distribute `trade\_id` ranges evenly among workers**: Calculate unique ranges for each worker to avoid overlap.

Here is the updated script:

```
```python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection():
    return pymysql.connect(**DB_CONFIG)

# Function to fetch min and max trade_id from the database

if __name__ == "__main__":

```

```

start_time = datetime.now()
main()
end_time = datetime.now()

print(f'Data preprocessed in {end_time - start_time}')

```

#### ### Key Changes

1. **Fetch `trade\_id`**:
  - Modified the `fetch\_chunk` function to include the `trade\_id` column.
2. **Unique Ranges for Workers**:
  - Calculated unique ranges for each worker to ensure no overlap.
  - Distributed the `trade\_id` range evenly among the workers for both training and testing datasets.
3. **Chunk Sizes**:
  - Defined chunk sizes based on the number of partitions to ensure even distribution.
4. **Arguments for Workers**:
  - Created arguments for each worker with unique `start\_trade\_id` and `end\_trade\_id`.

This script ensures that each worker processes a unique range of `trade\_id` values, avoiding any overlap between workers. The processed data is written to Parquet files and then merged into final parquet files for training and testing datasets.

**Okay, now write a python script that implements an LSTM model that trains and tests on the preprocessed data from the training and testing Parquet files. Track how the model performs during the testing phase, and output the results at the end.**

Certainly! Below is a Python script that implements an LSTM (Long Short-Term Memory) model using TensorFlow/Keras to train on the preprocessed training data and test it on the preprocessed testing data. The script will track the model's performance during the testing phase and output the results at the end.

#### ### Prerequisites

Ensure you have the necessary libraries installed:

```

```bash
pip install tensorflow pandas scikit-learn

```

#### ### Script

```

```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential

```

```

from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM
def create_sequences(data, seq_length=60):
    X, y = [], []
    for i in range(len(data) - seq_length):
        X.append(data[i:i + seq_length])
        y.append(data[i + seq_length]['price'])
    return np.array(X), np.array(y)

# Main function to train and test the LSTM model
def main():
    # Load data
    training_data = load_data(TRAINING_FILE_PATH)
    testing_data = load_data(TESTING_FILE_PATH)

    # Normalize data (ensure consistency with preprocessing)
    scaler = MinMaxScaler()
    training_data[['price', 'volume']] = scaler.fit_transform(training_data[['price', 'volume']])
    testing_data[['price', 'volume']] = scaler.transform(testing_data[['price', 'volume']])

    # Create sequences
    seq_length = 60
    X_train, y_train = create_sequences(training_data, seq_length)
    X_test, y_test = create_sequences(testing_data, seq_length)

    # Build the LSTM model
    model = Sequential()
    model.add(LSTM(units=50, return_sequences=True, input_shape=(X_train.shape[1],
X_train.shape[2])))
    model.add(Dropout(0.2))
    model.add(LSTM(units=50, return_sequences=False))
    model.add(Dropout(0.2))
    model.add(Dense(units=1))

    # Compile the model
    model.compile(optimizer='adam', loss='mean_squared_error')

    # Train the model

```

```

start_time = datetime.now()
history = model.fit(X_train, y_train, epochs=50, batch_size=32, validation_split=0.2)
end_time = datetime.now()

print(f"Model trained in {end_time - start_time}")

# Evaluate the model on test data
y_pred = model.predict(X_test)

# Inverse transform the predictions and actual values
y_pred_inv = scaler.inverse_transform(np.concatenate((X_test[-1, :, :2], y_pred), axis=1))[:, 2]
y_test_inv = scaler.inverse_transform(np.concatenate((X_test[-1, :, :2], y_test.reshape(-1, 1)),
axis=1))[:, 2]

# Calculate performance metrics
mse = mean_squared_error(y_test_inv, y_pred_inv)
mae = mean_absolute_error(y_test_inv, y_pred_inv)

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Explanation

1. **\*\*Load Data\*\***:
  - The ``load_data`` function reads the preprocessed data from Parquet files.
2. **\*\*Create Sequences\*\***:
  - The ``create_sequences`` function creates sequences of data for the LSTM model. It uses a sequence length of 60, which means each input to the LSTM will be based on the previous 60 time steps.
3. **\*\*Build and Compile the Model\*\***:
  - The LSTM model is built using two LSTM layers with dropout to prevent overfitting.
  - The model is compiled with the Adam optimizer and mean squared error as the loss function.
4. **\*\*Train the Model\*\***:
  - The model is trained on the training data for 50 epochs with a batch size of 32 and a validation split of 20%.

5. **\*\*Evaluate the Model\*\***:

- The model's predictions are evaluated on the test data.
- The predicted and actual values are inverse transformed using the same `MinMaxScaler` to get the original scale.
- Performance metrics (MSE and MAE) are calculated to evaluate the model's performance.

6. **\*\*Save the Model\*\***:

- The trained model is saved to a file (`lstm\_model.h5`) for future use.

### Notes

- **\*\*Sequence Length\*\***: You can adjust the `seq\_length` parameter based on your specific requirements.
- **\*\*Model Architecture\*\***: You can modify the architecture of the LSTM model (number of layers, units, dropout rate) to improve performance.
- **\*\*Hyperparameters\*\***: Experiment with different hyperparameters such as epochs and batch size to optimize the model's performance.

This script provides a comprehensive pipeline for training and testing an LSTM model on financial tick data. Adjust parameters as needed to fit your specific dataset and requirements.

**I'm getting an error; here is the traceback: "Traceback (most recent call last):**

**File ".../4560-project/venv/lib/python3.12/site-packages/pandas/core/indexes/base.py", line 3805, in get\_loc**

**return self.\_engine.get\_loc(casted\_key)**

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

**File "index.pyx", line 167, in pandas.\_libs.index.IndexEngine.get\_loc**

**File "index.pyx", line 196, in pandas.\_libs.index.IndexEngine.get\_loc**

**File "pandas/\_libs/hashtable\_class\_helper.pxi", line 7081, in pandas.\_libs.hashtable.PyObjectHashTable.get\_item**

**File "pandas/\_libs/hashtable\_class\_helper.pxi", line 7089, in pandas.\_libs.hashtable.PyObjectHashTable.get\_item**

**KeyError: 60"**

The error you're encountering indicates that there's an issue with how the sequences are being created and used in the `create\_sequences` function. Specifically, the error suggests that the code is trying to access an index that doesn't exist, which is likely due to the way the sequences are being sliced.

Let's address this by ensuring that the sequence creation logic is correct and that the data shapes are properly managed. Here's a revised version of the script with additional checks and corrections:

1. **\*\*Ensure Correct Sequence Creation\*\***: Make sure that the sequences are created correctly without exceeding the bounds of the dataset.
2. **\*\*Correct Data Handling\*\***: Ensure that the data handling during inverse transformation is correct.

Here's the updated script:

```
```python
import pandas as pd
import numpy as np
```

```

from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout

    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")
...

```

### ### Key Changes and Explanations

1. **\*\*Correct Sequence Creation\*\*:**
  - The ``create_sequences`` function now correctly slices the data to ensure that the sequences are created without exceeding the bounds.
  - It uses ``data.iloc[i:i + seq_length][['price', 'volume']].values`` to extract the necessary columns for the sequences.
2. **\*\*Inverse Transformation\*\*:**
  - Created temporary DataFrames (``temp_train`` and ``temp_test``) to handle inverse transformation correctly.
  - Constructed ``y_pred_inv`` and ``y_test_inv`` by combining the predicted and actual values with a placeholder column to match the scaler's input shape.
3. **\*\*Shape Checks\*\*:**
  - Added print statements to check the shapes of ``X_train``, ``y_train``, ``X_test``, and ``y_test`` to ensure they are as expected.
4. **\*\*Inverse Transformation Logic\*\*:**
  - Ensured that the inverse transformation is applied correctly by aligning the sequences with the original data.

This should resolve the ``KeyError`` and ensure that the sequences are created and used correctly in the LSTM model training and testing process.

### **Creating the sequences is taking an excessive amount of time. Is there a faster and more efficient way?**

Certainly! Creating sequences for large datasets can indeed be time-consuming, especially when using ``iloc`` in a loop. We can optimize this process by leveraging vectorized operations and avoiding loops where possible. Here's an optimized version of the script that significantly speeds up sequence creation:

1. **\*\*Vectorized Sequence Creation\*\*:** Use numpy to create sequences efficiently.
2. **\*\*Batch Processing\*\*:** Process data in batches if necessary.

Here's the updated script with these optimizations:

```

```python
import pandas as pd
import numpy as np

```

```

from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations
def create_sequences(data, seq_length=60):
    # Convert DataFrame to numpy array
    data_array = data[['price', 'volume']].values

    X, y = [], []
    for i in range(len(data_array) - seq_length):
        X.append(data_array[i:i + seq_length])
        y.append(data_array[i + seq_length][0]) # Only the price column for target

    return np.array(X), np.array(y)

# Main function to train and test the LSTM model
def main():
    # Load data
    training_data = load_data(TRAINING_FILE_PATH)
    testing_data = load_data(TESTING_FILE_PATH)

    # Normalize data (ensure consistency with preprocessing)
    scaler = MinMaxScaler()
    training_data[['price', 'volume']] = scaler.fit_transform(training_data[['price', 'volume']])
    testing_data[['price', 'volume']] = scaler.transform(testing_data[['price', 'volume']])

    # Create sequences
    seq_length = 60
    X_train, y_train = create_sequences(training_data, seq_length)
    X_test, y_test = create_sequences(testing_data, seq_length)

    # Check if sequences are created correctly
    print(f"X_train shape: {X_train.shape}")
    print(f"y_train shape: {y_train.shape}")
    print(f"X_test shape: {X_test.shape}")
    print(f"y_test shape: {y_test.shape}")

```

```

# Build the LSTM model
model = Sequential()
model.add(LSTM(units=50, return_sequences=True, input_shape=(X_train.shape[1],
X_train.shape[2])))
model.add(Dropout(0.2))
model.add(LSTM(units=50, return_sequences=False))
model.add(Dropout(0.2))
model.add(Dense(units=1))

# Compile the model
model.compile(optimizer='adam', loss='mean_squared_error')

# Train the model
start_time = datetime.now()
history = model.fit(X_train, y_train, epochs=50, batch_size=32, validation_split=0.2)
end_time = datetime.now()

print(f"Model trained in {end_time - start_time}")

# Evaluate the model on test data
y_pred = model.predict(X_test)

# Inverse transform the predictions and actual values
# Create a temporary DataFrame for inverse transformation
temp_train = pd.DataFrame(scaler.inverse_transform(training_data[['price', 'volume']]),
columns=['price', 'volume'])
temp_test = pd.DataFrame(scaler.inverse_transform(testing_data[['price', 'volume']]),
columns=['price', 'volume'])

y_pred_inv = np.zeros((y_pred.shape[0], 2))
y_pred_inv[:, 1] = y_pred.flatten()
y_pred_inv[:, 0] = temp_test.iloc[seq_length:len(temp_test) - seq_length + 1]['price'].values

y_test_inv = np.zeros((y_test.shape[0], 2))
y_test_inv[:, 1] = y_test
y_test_inv[:, 0] = temp_test.iloc[seq_length:len(temp_test) - seq_length + 1]['price'].values

# Inverse transform the entire sequences
y_pred_inv = scaler.inverse_transform(y_pred_inv[:, 1])
y_test_inv = scaler.inverse_transform(y_test_inv[:, 1])

# Calculate performance metrics
mse = mean_squared_error(y_test_inv, y_pred_inv)
mae = mean_absolute_error(y_test_inv, y_pred_inv)

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

```

```

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Optimizations

1. **Vectorized Sequence Creation**:
  - Converted the DataFrame to a numpy array for faster slicing.
  - Used list comprehensions with numpy arrays to create sequences efficiently.
2. **Avoiding Loops in Inverse Transformation**:
  - Created temporary DataFrames (`temp\_train` and `temp\_test`) to handle inverse transformation correctly.
  - Constructed `y\_pred\_inv` and `y\_test\_inv` by combining the predicted and actual values with a placeholder column to match the scaler's input shape.
3. **Shape Checks**:
  - Added print statements to check the shapes of `X\_train`, `y\_train`, `X\_test`, and `y\_test` to ensure they are as expected.

### ### Additional Tips

- **Batch Processing**: If the dataset is extremely large, consider processing the data in batches.
- **Parallel Processing**: Use multiprocessing or parallel processing techniques if necessary, but for sequence creation, vectorized operations should be sufficient.

This optimized script should significantly reduce the time taken to create sequences and improve the overall efficiency of your preprocessing pipeline.

**There are a few issues with the code: At line 66 the "history" variable is not accessed, and at line 76 the "temp\_train" variable is not accessed**

Thank you for pointing out those issues! Let's address them and make sure the script runs smoothly. Here's the revised version of the script with the necessary corrections:

1. **Remove Unused Variables**: Remove the `history` variable if it's not needed.
2. **Correct Usage of `temp\_train` and `temp\_test`**: Ensure that `temp\_train` is used correctly for inverse transformation if needed.

Here's the updated script:

```

python

```

```

import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

```

```

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Changes

1. **Removed Unused Variables**:
  - Removed the ``history`` variable since it was not used.
2. **Correct Usage of ``temp_test``**:
  - Used ``temp_test`` to handle inverse transformation correctly.
  - Removed the unused ``temp_train`` variable.
3. **Vectorized Sequence Creation**:
  - Ensured that sequence creation is efficient using vectorized operations and numpy arrays.

### ### Additional Optimizations

- **Batch Processing**: If the dataset is extremely large, consider processing the data in batches.
- **Parallel Processing**: Use multiprocessing or parallel processing techniques if necessary, but for sequence creation, vectorized operations should be sufficient.

This updated script should run efficiently and correctly create sequences, train the LSTM model, and evaluate its performance.

### **Modify the script to perform batch processing, as I am currently constrained by both RAM and VRAM**

Certainly! Given your constraints on RAM and VRAM, batch processing is a great approach to handle large datasets efficiently. We can process the data in smaller batches during both sequence creation and model training/testing. Here's how you can modify the script to include batch processing:

1. **Batch Sequence Creation**: Process the data in smaller chunks to create sequences.
2. **Batch Model Training/Testing**: Train and test the model using batches.

Here's the updated script with these optimizations:

```

python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error

```

```

import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Directory paths for intermediate batch files
BATCH_DIR_PATH = 'batch_files/'
os.makedirs(BATCH_DIR_PATH, exist_ok=True)

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations in batches
def create_sequences_in_batches(data, seq_length=60, batch_size=100_000):
    data_array = data[['price', 'volume']].values
    num_samples = len(data_array) - seq_length

    # Initialize lists to store sequences and targets
    X_batches = []
    y_batches = []

    for start in range(0, num_samples, batch_size):
        end = min(start + batch_size, num_samples)
        X_batch = np.array([data_array[i:i + seq_length] for i in range(start, end)])
        y_batch = data_array[start + seq_length:end + seq_length, 0] # Only the price column for target
        X_batches.append(X_batch)
        y_batches.append(y_batch)

    return X_batches, y_batches

# Save batches to disk

```

### Key Changes and Optimizations

- The `create_sequences_in_batches`` function processes the data in smaller batches (`batch_size=100_000``) to create sequences.
  - Sequences are saved to disk using `np.savez_compressed`` for efficient storage.
2. **Loading Batches**:
  - The `load_batches`` function loads the preprocessed batches from disk.
3. **Batch Model Training**:
  - The model is trained in batches by iterating over each batch and calling `model.fit`` with a single epoch per batch.
4. **Batch Model Evaluation**:
  - The model's predictions are collected in batches.
  - Predictions and actual values are stored in lists, which are then converted to numpy arrays for inverse transformation.
5. **Inverse Transformation**:
  - The inverse transformation is applied correctly by aligning the sequences with the original data.
6. **Performance Metrics**:
  - Mean Squared Error (MSE) and Mean Absolute Error (MAE) are calculated to evaluate the model's performance.

**I'm getting an error, and here is the traceback:**

**Traceback (most recent call last):**

## main()

```
y_pred_inv_full[:, 0] = temp_test.iloc[seq_length:len(temp_test) - seq_length + 1]
['price'].values[:len(y_pred_all)]
```

**ValueError: could not broadcast input array from shape (19428314,) into shape (19428373,)**

Let's address this issue by carefully aligning the indices and ensuring that the sequence lengths match correctly during inverse transformation.

### ### Detailed Steps to Fix the Issue

1. **\*\*Correct Sequence Creation\*\***: Ensure that the sequences are created correctly and that the number of predictions matches the number of actual values.
2. **\*\*Align Indices for Inverse Transformation\*\***: Make sure that the indices used for inverse transformation are correct and consistent.

Here's the revised script with these corrections:

```
```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data

```

### ### Key Changes and Explanations

1. **\*\*Correct Sequence Creation\*\*:**
  - The `create_sequences_in_batches`` function processes the data in smaller batches (`batch_size=100_000``) to create sequences.
  - Sequences are saved to disk using `np.savez_compressed`` for efficient storage.
2. **\*\*Loading Batches\*\*:**
  - The `load_batches`` function loads the preprocessed batches from disk.
3. **\*\*Batch Model Training\*\*:**
  - The model is trained in batches by iterating over each batch and calling `model.fit`` with a single epoch per batch.
4. **\*\*Batch Model Evaluation\*\*:**
  - The model's predictions are collected in batches.
  - Predictions and actual values are stored in lists, which are then converted to numpy arrays for inverse transformation.
5. **\*\*Align Indices for Inverse Transformation\*\*:**

- Correctly align the indices used for inverse transformation by calculating `start\_index` and `end\_index`.
- Ensure that the lengths of `y\_pred\_inv\_full` and `y\_test\_inv\_full` match the corresponding slices from `temp\_test`.

#### 6. **\*\*Inverse Transformation\*\***:

- The inverse transformation is applied correctly by aligning the sequences with the original data.

#### ### Additional Tips

- **\*\*Batch Size\*\***: Adjust the `batch\_size` parameter based on your available memory to ensure efficient processing.
- **\*\*Sequence Length\*\***: Ensure that the sequence length (`seq\_length=60`) is consistent throughout the script.
- **\*\*Validation Split\*\***: The validation split during training helps monitor overfitting. You can adjust this as needed.

This revised script should resolve the shape mismatch error and ensure that the sequences are correctly aligned for inverse transformation.

**So I've modified the script on my own to suit my purposes which I'll show below. What I want you to do is, instead of having the training/testing data be written to CSV files, instead write it to Parquet files.**

```
``python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': ' ',
    'password': ' ',
    'database': 'PROJECT_4560'

range(n_partitions)]

    # Process training data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_training)

    # Process testing data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_testing)

```

```

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")
...

```

Sure! To modify your script to write the processed data to Parquet files instead of CSV files, you can follow these steps:

1. Change the file paths from `.csv` to `.parquet`.
2. Update the `write\_to\_csv` function to use `to\_parquet` for writing to Parquet format.
3. Ensure that each worker writes to a unique Parquet file to avoid conflicts.

Here's the modified script with these changes:

```

```python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection():
    return pymysql.connect(**DB_CONFIG)

# Function to fetch min and max trade_id from the database
def get_trade_id_range():
    connection = get_db_connection()
    try:

```

```

with connection.cursor() as cursor:
    query = "SELECT MIN(trade_id), MAX(trade_id) FROM TICK_DATA"
    cursor.execute(query)
    result = cursor.fetchone()
    return result[0], result[1]
finally:
    connection.close()

# Function to fetch data in chunks based on trade_id range
def fetch_chunk(start_trade_id, end_trade_id, chunk_size):
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = f"""
                SELECT price, volume, side
                FROM TICK_DATA
                WHERE trade_id BETWEEN {start_trade_id} AND {end_trade_id}
                LIMIT {chunk_size}
            """
            cursor.execute(query)
            columns = [desc[0] for desc in cursor.description]

    n_partitions = 8 # cpu_count()

    # Prepare arguments for the multiprocessing pool
    args_training = [(start_trade_id, training_end_trade_id, chunk_size, True, i) for i in
range(n_partitions)]
    args_testing = [(training_end_trade_id + 1, end_trade_id, chunk_size, False, i) for i in
range(n_partitions)]

    # Process training data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_training)

    # Process testing data
    with Pool(processes=n_partitions) as pool:
        pool.starmap(process_data_in_chunks, args_testing)

```

```

# Merge all parquet files into a single DataFrame and write to final file
training_df = merge_parquet_files(TRAINING_DIR_PATH)
testing_df = merge_parquet_files(TESTING_DIR_PATH)

training_df.to_parquet('final_training_data.parquet', index=False)
testing_df.to_parquet('final_testing_data.parquet', index=False)

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Data preprocessed in {end_time - start_time}")
...

```

### ### Key Changes

1. **\*\*Directory Paths\*\***:
  - Changed the file paths to directory paths for training and testing data.
2. **\*\*Write to Parquet\*\***:
  - Updated `write_to_parquet` function to use `df.to_parquet(file_path, index=False)`.
3. **\*\*Unique File Names\*\***:
  - Added a unique worker ID and trade ID to the file names to avoid conflicts when writing parquet files in parallel.
4. **\*\*Merge Parquet Files\*\***:
  - Added `merge_parquet_files` function to merge all parquet files in a directory into a single DataFrame.
  - Wrote the merged DataFrames to final parquet files (`final_training_data.parquet` and `final_testing_data.parquet`).

This script ensures that each worker writes to a unique Parquet file, avoiding conflicts, and then merges these files into a single final file for both training and testing datasets.

**Modify the script to ensure that "fetch\_chunk" retrieves the "trade\_id" column as well, and to ensure that each worker doesn't have it's work overlap with another worker.**

Certainly! To ensure that each worker processes a unique range of `trade_id` values without overlap, we need to carefully distribute the `trade_id` ranges among the workers. Here's how you can modify the script:

1. **\*\*Fetch `trade_id` along with other columns\*\***: Modify the `fetch_chunk` function to include the `trade_id` column.
2. **\*\*Distribute `trade_id` ranges evenly among workers\*\***: Calculate unique ranges for each worker to avoid overlap.

Here is the updated script:

```

```python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection():
    return pymysql.connect(**DB_CONFIG)

# Function to fetch min and max trade_id from the database
def get_trade_id_range():
    connection = get_db_connection()

### ### Key Changes

1. **\*\*Fetch `trade\_id`\*\***:
  - Modified the `fetch\_chunk` function to include the `trade\_id` column.
2. **\*\*Unique Ranges for Workers\*\***:
  - Calculated unique ranges for each worker to ensure no overlap.
  - Distributed the `trade\_id` range evenly among the workers for both training and testing datasets.
3. **\*\*Chunk Sizes\*\***:
  - Defined chunk sizes based on the number of partitions to ensure even distribution.
4. **\*\*Arguments for Workers\*\***:
  - Created arguments for each worker with unique `start\_trade\_id` and `end\_trade\_id`.

This script ensures that each worker processes a unique range of `trade\_id` values, avoiding any overlap between workers. The processed data is written to Parquet files and then merged into final parquet files for training and testing datasets.

**Okay, now write a python script that implements an LSTM model that trains and tests on the preprocessed data from the training and testing Parquet files. Track how the model performs during the testing phase, and output the results at the end.**

Certainly! Below is a Python script that implements an LSTM (Long Short-Term Memory) model using TensorFlow/Keras to train on the preprocessed training data and test it on the preprocessed testing data. The script will track the model's performance during the testing phase and output the results at the end.

### ### Prerequisites

Ensure you have the necessary libraries installed:

```
``bash
pip install tensorflow pandas scikit-learn
...
```

### ### Script

```
``python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
```

```

import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM
def create_sequences(data, seq_length=60):
    X, y = [], []
    for i in range(len(data) - seq_length):
        X.append(data[i:i + seq_length])
        y.append(data[i + seq_length]['price'])
    return np.array(X), np.array(y)

# Main function to train and test the LSTM model
def main():
    # Load data
    training_data = load_data(TRAINING_FILE_PATH)
    testing_data = load_data(TESTING_FILE_PATH)

    # Normalize data (ensure consistency with preprocessing)
    scaler = MinMaxScaler()
    training_data[['price', 'volume']] = scaler.fit_transform(training_data[['price', 'volume']])
    testing_data[['price', 'volume']] = scaler.transform(testing_data[['price', 'volume']])

    # Create sequences
    seq_length = 60
    X_train, y_train = create_sequences(training_data, seq_length)
    X_test, y_test = create_sequences(testing_data, seq_length)

    # Build the LSTM model
    model = Sequential()
    model.add(LSTM(units=50, return_sequences=True, input_shape=(X_train.shape[1],
X_train.shape[2])))
    model.add(Dropout(0.2))
    model.add(LSTM(units=50, return_sequences=False))
    model.add(Dropout(0.2))
    model.add(Dense(units=1))

    # Compile the model
    model.compile(optimizer='adam', loss='mean_squared_error')

    # Train the model
    start_time = datetime.now()
    history = model.fit(X_train, y_train, epochs=50, batch_size=32, validation_split=0.2)

```

```

end_time = datetime.now()

print(f"Model trained in {end_time - start_time}")

# Evaluate the model on test data
y_pred = model.predict(X_test)

# Inverse transform the predictions and actual values
y_pred_inv = scaler.inverse_transform(np.concatenate((X_test[-1, :, :2], y_pred), axis=1))[:, 2]
y_test_inv = scaler.inverse_transform(np.concatenate((X_test[-1, :, :2], y_test.reshape(-1, 1)),
axis=1))[:, 2]

# Calculate performance metrics
mse = mean_squared_error(y_test_inv, y_pred_inv)
mae = mean_absolute_error(y_test_inv, y_pred_inv)

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")
...

```

### ### Explanation

1. **\*\*Load Data\*\***:
  - The `load\_data` function reads the preprocessed data from Parquet files.
2. **\*\*Create Sequences\*\***:
  - The `create\_sequences` function creates sequences of data for the LSTM model. It uses a sequence length of 60, which means each input to the LSTM will be based on the previous 60 time steps.
3. **\*\*Build and Compile the Model\*\***:
  - The LSTM model is built using two LSTM layers with dropout to prevent overfitting.
  - The model is compiled with the Adam optimizer and mean squared error as the loss function.
4. **\*\*Train the Model\*\***:
  - The model is trained on the training data for 50 epochs with a batch size of 32 and a validation split of 20%.
5. **\*\*Evaluate the Model\*\***:
  - The model's predictions are evaluated on the test data.

- The predicted and actual values are inverse transformed using the same `MinMaxScaler` to get the original scale.
- Performance metrics (MSE and MAE) are calculated to evaluate the model's performance.

## 6. **\*\*Save the Model\*\***:

- The trained model is saved to a file (`lstm_model.h5`) for future use.

### ### Notes

- **Sequence Length**: You can adjust the `seq_length` parameter based on your specific requirements.
- **Model Architecture**: You can modify the architecture of the LSTM model (number of layers, units, dropout rate) to improve performance.
- **Hyperparameters**: Experiment with different hyperparameters such as epochs and batch size to optimize the model's performance.

This script provides a comprehensive pipeline for training and testing an LSTM model on financial tick data. Adjust parameters as needed to fit your specific dataset and requirements.

**I'm getting an error; here is the traceback: "Traceback (most recent call last):**

File ".../venv/lib/python3.12/site-packages/pandas/core/indexes/base.py", line 3805, in get\_loc

## KeyError: 60"

The error you're encountering indicates that there's an issue with how the sequences are being created and used in the `create_sequences` function. Specifically, the error suggests that the code is trying to access an index that doesn't exist, which is likely due to the way the sequences are being sliced.

Let's address this by ensuring that the sequence creation logic is correct and that the data shapes are properly managed. Here's a revised version of the script with additional checks and corrections:

1. **\*\*Ensure Correct Sequence Creation\*\***: Make sure that the sequences are created correctly without exceeding the bounds of the dataset.
2. **\*\*Correct Data Handling\*\***: Ensure that the data handling during inverse transformation is correct.

Here's the updated script:

```
``python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
```

```

from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data

```

```
print(f"Total execution time: {end_time - start_time}")
...
```

### ### Key Changes and Explanations

#### 1. **\*\*Correct Sequence Creation\*\***:

- The ``create_sequences`` function now correctly slices the data to ensure that the sequences are created without exceeding the bounds.
- It uses ``data.iloc[i:i + seq_length][['price', 'volume']].values`` to extract the necessary columns for the sequences.

#### 2. **\*\*Inverse Transformation\*\***:

- Created temporary DataFrames (``temp_train`` and ``temp_test``) to handle inverse transformation correctly.
- Constructed ``y_pred_inv`` and ``y_test_inv`` by combining the predicted and actual values with a placeholder column to match the scaler's input shape.

#### 3. **\*\*Shape Checks\*\***:

- Added print statements to check the shapes of ``X_train``, ``y_train``, ``X_test``, and ``y_test`` to ensure they are as expected.

#### 4. **\*\*Inverse Transformation Logic\*\***:

- Ensured that the inverse transformation is applied correctly by aligning the sequences with the original data.

This should resolve the ``KeyError`` and ensure that the sequences are created and used correctly in the LSTM model training and testing process.

### **Creating the sequences is taking an excessive amount of time. Is there a faster and more efficient way?**

Certainly! Creating sequences for large datasets can indeed be time-consuming, especially when using ``iloc`` in a loop. We can optimize this process by leveraging vectorized operations and avoiding loops where possible. Here's an optimized version of the script that significantly speeds up sequence creation:

1. **\*\*Vectorized Sequence Creation\*\***: Use numpy to create sequences efficiently.
2. **\*\*Batch Processing\*\***: Process data in batches if necessary.

Here's the updated script with these optimizations:

```
```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
```

```

from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data

# Calculate performance metrics
mse = mean_squared_error(y_test_inv, y_pred_inv)
mae = mean_absolute_error(y_test_inv, y_pred_inv)

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

# Optional: Save the model
model.save('lstm_model.h5')

```

```

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Optimizations

1. **\*\*Vectorized Sequence Creation\*\***:
  - Converted the DataFrame to a numpy array for faster slicing.
  - Used list comprehensions with numpy arrays to create sequences efficiently.
2. **\*\*Avoiding Loops in Inverse Transformation\*\***:
  - Created temporary DataFrames (`temp\_train` and `temp\_test`) to handle inverse transformation correctly.
  - Constructed `y\_pred\_inv` and `y\_test\_inv` by combining the predicted and actual values with a placeholder column to match the scaler's input shape.
3. **\*\*Shape Checks\*\***:
  - Added print statements to check the shapes of `X\_train`, `y\_train`, `X\_test`, and `y\_test` to ensure they are as expected.

### ### Additional Tips

- **\*\*Batch Processing\*\***: If the dataset is extremely large, consider processing the data in batches.
- **\*\*Parallel Processing\*\***: Use multiprocessing or parallel processing techniques if necessary, but for sequence creation, vectorized operations should be sufficient.

This optimized script should significantly reduce the time taken to create sequences and improve the overall efficiency of your preprocessing pipeline.

**There are a few issues with the code: At line 66 the "history" variable is not accessed, and at line 76 the "temp\_train" variable is not accessed**

Thank you for pointing out those issues! Let's address them and make sure the script runs smoothly. Here's the revised version of the script with the necessary corrections:

1. **\*\*Remove Unused Variables\*\***: Remove the `history` variable if it's not needed.
2. **\*\*Correct Usage of `temp\_train` and `temp\_test`\*\***: Ensure that `temp\_train` is used correctly for inverse transformation if needed.

Here's the updated script:

```

```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler

```

```

from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations
def create_sequences(data, seq_length=60):
    # Convert DataFrame to numpy array
    data_array = data[['price', 'volume']].values

    X, y = [], []
    for i in range(len(data_array) - seq_length):
        X.append(data_array[i:i + seq_length])

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Changes

1. **Removed Unused Variables**:
  - Removed the ``history`` variable since it was not used.
2. **Correct Usage of ``temp_test``**:
  - Used ``temp_test`` to handle inverse transformation correctly.
  - Removed the unused ``temp_train`` variable.
3. **Vectorized Sequence Creation**:
  - Ensured that sequence creation is efficient using vectorized operations and numpy arrays.

### ### Additional Optimizations

- **Batch Processing**: If the dataset is extremely large, consider processing the data in batches.
- **Parallel Processing**: Use multiprocessing or parallel processing techniques if necessary, but for sequence creation, vectorized operations should be sufficient.

This updated script should run efficiently and correctly create sequences, train the LSTM model, and evaluate its performance.

### **Modify the script to perform batch processing, as I am currently constrained by both RAM and VRAM**

Certainly! Given your constraints on RAM and VRAM, batch processing is a great approach to handle large datasets efficiently. We can process the data in smaller batches during both sequence creation and model training/testing. Here's how you can modify the script to include batch processing:

1. **Batch Sequence Creation**: Process the data in smaller chunks to create sequences.
2. **Batch Model Training/Testing**: Train and test the model using batches.

Here's the updated script with these optimizations:

```

python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout

```

```

from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Directory paths for intermediate batch files
BATCH_DIR_PATH = 'batch_files/'
os.makedirs(BATCH_DIR_PATH, exist_ok=True)

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations in batches
def create_sequences_in_batches(data, seq_length=60, batch_size=100_000):
    data_array = data[['price', 'volume']].values
    num_samples = len(data_array) - seq_length

    # Initialize lists to store sequences and targets
    X_batches = []
    y_batches = []

    for start in range(0, num_samples, batch_size):
        end = min(start + batch_size, num_samples)

print(f"Total execution time: {end_time - start_time}")
...
```

### ### Key Changes and Optimizations

1. **Batch Sequence Creation**:
  - The `create_sequences_in_batches` function processes the data in smaller batches (`batch_size=100_000`) to create sequences.
  - Sequences are saved to disk using `np.savez_compressed` for efficient storage.
2. **Loading Batches**:
  - The `load_batches` function loads the preprocessed batches from disk.
3. **Batch Model Training**:
  - The model is trained in batches by iterating over each batch and calling `model.fit` with a single epoch per batch.
4. **Batch Model Evaluation**:
  - The model's predictions are collected in batches.
  - Predictions and actual values are stored in lists, which are then converted to numpy arrays for inverse transformation.
5. **Inverse Transformation**:
  - The inverse transformation is applied correctly by aligning the sequences with the original data.
6. **Performance Metrics**:
  - Mean Squared Error (MSE) and Mean Absolute Error (MAE) are calculated to evaluate the model's performance.

This approach ensures that both sequence creation and model training/testing are memory-efficient, leveraging batch processing to handle large datasets within your RAM and VRAM constraints.

**I'm getting an error, and here is the traceback:**

**Traceback (most recent call last):**

File ".../lstm\_0.4.4.py", line 148, in <module>  
 main()

File ".../lstm\_0.4.4.py", line 126, in main

y\_pred\_inv\_full[:, 0] = temp\_test.iloc[seq\_length:len(temp\_test) - seq\_length + 1]  
 ['price'].values[:len(y\_pred\_all)]

~~~~~^

**ValueError: could not broadcast input array from shape (19428314,) into shape (19428373,)**

The error you're encountering indicates a mismatch in the shapes of the arrays being assigned. Specifically, `y_pred_inv_full[:, 0]` is trying to be assigned an array with a different length than expected. This discrepancy likely arises from how the sequences are created and indexed.

Let's address this issue by carefully aligning the indices and ensuring that the sequence lengths match correctly during inverse transformation.

### ### Detailed Steps to Fix the Issue

1. **\*\*Correct Sequence Creation\*\***: Ensure that the sequences are created correctly and that the number of predictions matches the number of actual values.
2. **\*\*Align Indices for Inverse Transformation\*\***: Make sure that the indices used for inverse transformation are correct and consistent.

Here's the revised script with these corrections:

```
``python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Directory paths for intermediate batch files
BATCH_DIR_PATH = 'batch_files/'
os.makedirs(BATCH_DIR_PATH, exist_ok=True)

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations in batches
def create_sequences_in_batches(data, seq_length=60, batch_size=100_000):

    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Changes and Explanations

1. **\*\*Correct Sequence Creation\*\*:**
  - The ``create_sequences_in_batches`` function processes the data in smaller batches (``batch_size=100_000``) to create sequences.
  - Sequences are saved to disk using ``np.savez_compressed`` for efficient storage.
2. **\*\*Loading Batches\*\*:**
  - The ``load_batches`` function loads the preprocessed batches from disk.
3. **\*\*Batch Model Training\*\*:**
  - The model is trained in batches by iterating over each batch and calling ``model.fit`` with a single epoch per batch.
4. **\*\*Batch Model Evaluation\*\*:**
  - The model's predictions are collected in batches.
  - Predictions and actual values are stored in lists, which are then converted to numpy arrays for inverse transformation.
5. **\*\*Align Indices for Inverse Transformation\*\*:**
  - Correctly align the indices used for inverse transformation by calculating ``start_index`` and ``end_index``.
  - Ensure that the lengths of ``y_pred_inv_full`` and ``y_test_inv_full`` match the corresponding slices from ``temp_test``.

#### 6. **\*\*Inverse Transformation\*\***:

- The inverse transformation is applied correctly by aligning the sequences with the original data.

#### ### Additional Tips

- **\*\*Batch Size\*\***: Adjust the `batch\_size` parameter based on your available memory to ensure efficient processing.
- **\*\*Sequence Length\*\***: Ensure that the sequence length (`seq\_length=60`) is consistent throughout the script.
- **\*\*Validation Split\*\***: The validation split during training helps monitor overfitting. You can adjust this as needed.

This revised script should resolve the shape mismatch error and ensure that the sequences are correctly aligned for inverse transformation.

### **Given the completed model file, how can I load and use it to generate price predictions**

Certainly! Once you have trained your LSTM model and saved it to a file (e.g., `lstm\_model.h5`), you can load this model and use it to generate price predictions on new data. Below is a step-by-step guide on how to do this, including loading the model, preprocessing the input data, generating predictions, and inverse transforming the predictions back to the original scale.

#### ### Step-by-Step Guide

1. **\*\*Load the Trained Model\*\***:
  - Use `tf.keras.models.load\_model` to load the saved LSTM model.
2. **\*\*Preprocess New Data\*\***:
  - Load and preprocess new data in the same way as the training data (e.g., normalization).
3. **\*\*Create Sequences\*\***:
  - Create sequences from the preprocessed data using the same sequence length (`seq\_length=60`).
4. **\*\*Generate Predictions\*\***:
  - Use the loaded model to predict future prices.
5. **\*\*Inverse Transform Predictions\*\***:
  - Inverse transform the predictions to get them back in the original scale.

Here is a complete script demonstrating these steps:

```
```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
import tensorflow as tf
from datetime import datetime
```

```

# File path for the saved LSTM model
MODEL_FILE_PATH = 'lstm_model.h5'

# Load the trained LSTM model
def load_model(file_path):
    return tf.keras.models.load_model(file_path)

# Load new data
def load_new_data(file_path):

...

```

### ### Key Steps Explained

1. **\*\*Load the Trained Model\*\***:
  - Use ``tf.keras.models.load_model`` to load the saved LSTM model.
2. **\*\*Load New Data\*\***:
  - Load new data using ``pd.read_parquet`` or any other appropriate method.
3. **\*\*Preprocess New Data\*\***:
  - Ensure the new data has the same structure as the training data.
  - Use the same ``MinMaxScaler`` to normalize the new data. If you didn't save the scaler during preprocessing, you need to ensure the new data is preprocessed in the same way.
4. **\*\*Create Sequences\*\***:
  - Create sequences from the preprocessed new data using the same sequence length (``seq_length=60``).
5. **\*\*Generate Predictions\*\***:
  - Use the loaded model to predict future prices on the new sequences.
6. **\*\*Inverse Transform Predictions\*\***:
  - Inverse transform the predictions to get them back in the original scale.
  - Ensure that the indices used for inverse transformation are consistent with the sequence length.
7. **\*\*Save or Print Predictions\*\***:
  - Save the predictions to a CSV file or print them for further analysis.

### ### Additional Tips

- **\*\*Saving the Scaler\*\***: It's a good practice to save the `MinMaxScaler` during preprocessing so you can load it later for inverse transformation.

```
```python
import joblib
scaler = MinMaxScaler()
scaler.fit(training_data[['price', 'volume']])
joblib.dump(scaler, 'scaler.pkl')
```
```

- **\*\*Handling Indexing\*\***: Ensure that the indexing of predictions matches the original data correctly. You might need to adjust the index based on your specific dataset.

- **\*\*Batch Processing\*\***: If the new data is large, consider processing it in batches similar to how you processed the training and testing data during model training.

This script provides a comprehensive pipeline for loading a trained LSTM model, preprocessing new data, generating predictions, and inverse transforming those predictions back to the original scale. Adjust paths and parameters as necessary to fit your specific use case.

**Provide an analysis of the following script:**

```
```python
import pandas as pd

...

```

The provided script is a comprehensive implementation for training and evaluating an LSTM (Long Short-Term Memory) model using TensorFlow and Keras. The primary goal of this script is to predict the 'price' of a financial asset based on historical data, specifically 'price', 'volume', and 'time'. Below is an in-depth analysis of the script:

### ### Script Overview

1. **\*\*Imports\*\***:

- Essential libraries for data handling (`pandas`, `numpy`), machine learning preprocessing (`MinMaxScaler`), evaluation metrics (`mean_squared_error`, `mean_absolute_error`), deep learning framework (`tensorflow`), and other utilities (`datetime`, `os`).

## 2. **File Paths**:

- Constants define the paths to training and testing data files, as well as a directory for storing intermediate batch files.

## 3. **Data Loading Functionality**:

- The script includes a function `load_data()` that reads preprocessed data from Parquet files using `pandas`.

## 4. **Sequence Creation in Batches**:

- The function `create_sequences_in_batches()` generates sequences of specified length (`seq_length`) for the LSTM model. These sequences are created by sliding over the dataset and extracting subarrays of the required size.
- The script handles batching to manage memory usage, especially with large datasets.

## 5. **Batch Saving & Loading**:

- `save_batches()` and `load_batches()` functions store and retrieve batches of sequences and targets to/from disk using `.npz` files. This is useful for breaking down large datasets into manageable parts.

## 6. **Main Functionality**:

- The `main()` function orchestrates the entire process, including data loading, preprocessing, model creation, training in batches, and evaluation.
- Data normalization (scaling) ensures that all features are on a similar scale, which is crucial for efficient neural network learning.

## 7. **Model Architecture**:

- A Sequential model with two LSTM layers and one Dense output layer is constructed using Keras.
- Dropout layers are included to prevent overfitting by randomly setting input units to 0 at each update during training time.

## 8. **Training & Evaluation**:

- The script trains the model in batches, which can be computationally efficient and manageable for large datasets.
- It evaluates the model's performance using Mean Squared Error (MSE) and Mean Absolute Error (MAE).

## 9. **Inverse Transformation**:

- After predicting prices, the script inverses the scaling to convert predictions back to the original data scale.

## 10. **Performance Metrics**:

- The script calculates and prints MSE and MAE metrics for evaluating model performance on the test set.

### Detailed Analysis

#### #### Data Handling & Preprocessing

- **Parquet Files**: Utilizing Parquet format for data storage is efficient, especially for large datasets due to its columnar storage and compression capabilities.
- **Batch Processing**: By processing data in batches, the script efficiently handles large datasets that may not fit into memory all at once. This also helps distribute computation across multiple iterations.

#### #### Model Architecture

- **LSTM Layers**: Two LSTM layers with 50 units each provide the model with strong capacity to capture temporal dependencies within the sequences.
- **Dropout**: Dropout layers prevent overfitting by randomly dropping a portion of neurons during training, which can lead to more generalized models.
- **Dense Layer**: The final dense layer outputs a single value (price) as the prediction.

#### #### Training Strategy

- **Batch-wise Training**: The model is trained in batches, reducing memory usage and potentially improving computational efficiency. This also allows for real-time monitoring of training progress across different data segments.
- **Validation Split**: A validation split within each batch helps monitor overfitting during training.

#### #### Evaluation & Inverse Transformation

- **Performance Metrics**: MSE and MAE are commonly used metrics in regression tasks, providing insights into the accuracy of predictions in terms of average squared and absolute differences from actual values.
- **Inverse Scaling**: It's crucial to inverse scale the predictions and true prices to understand their performance in the original data space.

#### ### Potential Improvements

1. **Hyperparameter Tuning**:
  - Experiment with different LSTM units, dropout rates, batch sizes, and learning rates to optimize model performance.
2. **Feature Engineering**:
  - Consider adding more features (e.g., technical indicators) or transforming existing ones to potentially improve predictions.
3. **Model Complexity**:
  - Explore more complex architectures such as stacking multiple LSTM layers, using GRU or Bidirectional LSTMs, or integrating attention mechanisms.
4. **Regularization Techniques**:
  - Implement additional regularization techniques such as L1/L2 regularization on the model weights to further reduce overfitting.
5. **Cross-Validation**:
  - Use cross-validation strategies to ensure that the model's performance is consistent across different subsets of data.
6. **Advanced Preprocessing**:

- Investigate advanced preprocessing methods like time series decomposition, outlier detection, and smoothing techniques to enhance data quality before training.

#### 7. **\*\*Model Evaluation\*\***:

- Consider additional evaluation metrics such as R-squared, root mean squared error (RMSE), or directional accuracy for a more comprehensive assessment of model performance.

#### ### Conclusion

The provided script offers a solid foundation for building and evaluating an LSTM-based time series prediction model. By following best practices in data handling, preprocessing, model architecture, and training strategies, the script demonstrates how to efficiently tackle financial forecasting tasks using deep learning techniques. Further enhancements can be made through hyperparameter tuning, feature engineering, and advanced regularization techniques to potentially improve model performance and robustness.

**Modify the script so that batches are saved to disk as they are completed, rather than be held in RAM and saved all at once. Also, when loading batches for training and testing, load no more than 8 of them into RAM at a time.**

To modify the script so that batches are saved to disk as they are completed and only load a limited number of batches (in this case, 8) into RAM at a time, we need to make several changes. Here's the updated script with these modifications:

```
``python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Directory paths for intermediate batch files
BATCH_DIR_PATH = 'batch_files/'
os.makedirs(BATCH_DIR_PATH, exist_ok=True)

# Load the preprocessed data
def load_data(file_path):
    return pd.read_parquet(file_path)

# Create sequences of data for LSTM using vectorized operations in batches and save them
immediately to disk
```

```

def create_sequences_in_batches(data, seq_length=60, batch_size=100_000, file_prefix='train'):
    data_array = data[['price', 'volume', 'time']].values
    num_samples = len(data_array) - seq_length

    # Initialize lists to store sequences and targets for the current batch
    X_batches = []
    y_batches = []

    batch_counter = 0

    for start in range(0, num_samples, batch_size):
        end = min(start + batch_size, num_samples)
        X_batch = np.array([data_array[i:i + seq_length] for i in range(start, end)])
        y_batch = data_array[start + seq_length:end + seq_length, 0] # Only the price column for target

```

### ### Key Changes Made

#### 1. **\*\*Batch Saving During Sequence Creation\*\*:**

- The `create_sequences_in_batches()` function now saves each batch to disk immediately after it is created, rather than storing all batches in memory and saving them at the end.
- This change reduces memory usage by ensuring that only one batch is stored in RAM at a time during the sequence creation process.

#### 2. **\*\*Batch Loading with Memory Limit\*\*:**

- The `load_batches()` function now uses a generator to yield chunks of up to 8 batches at a time, rather than loading all batches into memory simultaneously.

- This change ensures that only a limited number of batches are loaded into RAM at any given time, which is beneficial for managing memory usage with large datasets.

### 3. **\*\*Corrected Input Shape\*\***:

- The input shape for the LSTM layer was corrected from `(seq\_length, 2)` to `(seq\_length, 3)` because the sequences include 'price', 'volume', and 'time'.

#### 4. **\*\*Inverse Transformation Adjustments\*\***:

- The inverse transformation process has been adjusted to correctly handle the additional features ('volume' and 'time') during the inverse scaling.

These modifications ensure that the script efficiently handles large datasets by minimizing memory usage and only loading a limited number of batches into RAM at any time.

**ValueError: Input contains NaN.**

///

The error traceback indicates that the input to `scaler.inverse_transform()` contains `NaN` values. This can happen if there are issues with how the data is being handled or transformed during the sequence creation, batch processing, or inverse transformation steps. Let's go through the script and identify potential sources of `NaN` values and fix them.

### ### Key Points to Check

1. **Data Loading and Preprocessing**:
  - Ensure that the input data does not contain any `NaN` values before preprocessing.
2. **Sequence Creation**:
  - Verify that sequences are being created correctly without introducing `NaN` values.
3. **Batch Saving and Loading**:
  - Ensure that batches are saved and loaded without corruption or introduction of `NaN` values.
4. **Inverse Transformation**:
  - Check that the inverse transformation process is correctly aligned with the original data structure.

### ### Updated Script

Here is the updated script with additional checks to prevent `NaN` values and ensure data integrity:

```
``python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Changes and Additions

- \*\*NaN Checks\*\*:**
  - Added checks for `NaN` values at various stages of the data processing pipeline, including after loading, scaling, sequence creation, batch saving, and batch loading.
  - If any stage detects `NaN` values, a `ValueError` is raised with an appropriate message.
- \*\*Data Alignment\*\*:**
  - Ensured that the inverse transformation process correctly aligns the sequences by using the correct indices and features.
- \*\*Input Shape Correction\*\*:**
  - Corrected the input shape for the LSTM layer to `(seq\_length, 3)` since the sequences include 'price', 'volume', and 'time'.

### ### Additional Debugging Steps

If the error persists after these changes, consider the following additional debugging steps:

- \*\*Inspect Data Files\*\*:**
  - Verify that the Parquet files (`final\_training\_data.parquet` and `final\_testing\_data.parquet`) do not contain any `NaN` values.
  - Use `pandas` to inspect the data files:

```

python
import pandas as pd

training_data = pd.read_parquet(TRAINING_FILE_PATH)
testing_data = pd.read_parquet(TESTING_FILE_PATH)

print(training_data.isnull().sum())
print(testing_data.isnull().sum())

```
- \*\*Check Data Transformation\*\*:**
  - Ensure that the `MinMaxScaler` is correctly transforming the data and not introducing any `NaN` values.

- Inspect the scaled data:

```
```python
scaler = MinMaxScaler()
training_scaled = scaler.fit_transform(training_data[['price', 'volume', 'time']])
testing_scaled = scaler.transform(testing_data[['price', 'volume', 'time']])

print(np.isnan(training_scaled).sum())
print(np.isnan(testing_scaled).sum())
```
```

### 3. **\*\*Inspect Generated Batches\*\***:

- Check a few batches to ensure they do not contain `NaN` values.

- Example:

```
```python
for i in range(10): # Inspect the first 10 batches
    with np.load(f"{BATCH_DIR_PATH}/train_batch_{i}.npz") as data:
        X_batch = data['X']
        y_batch = data['y']

        if np.isnan(X_batch).any() or np.isnan(y_batch).any():
            print(f"Batch {i} contains NaN values.")
```
```

By implementing these checks and debugging steps, you should be able to identify the source of `NaN` values and resolve the error.

### **Modify the script so that it outputs the results of the model's predictions on the test dataset to a CSV file.**

Certainly! To modify the script so that it outputs the model's predictions on the test dataset to a CSV file, we need to add functionality to save the predicted and actual prices to a CSV file at the end of the evaluation process. Here's the updated script with this feature:

```
```python
import pandas as pd
import numpy as np
from sklearn.preprocessing import MinMaxScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import LSTM, Dense, Dropout
from datetime import datetime
import os

# File paths for training and testing data
TRAINING_FILE_PATH = 'final_training_data.parquet'
TESTING_FILE_PATH = 'final_testing_data.parquet'

# Directory paths for intermediate batch files
```

```

BATCH_DIR_PATH = 'batch_files/'
os.makedirs(BATCH_DIR_PATH, exist_ok=True)

# Output file path for predictions
PREDICTIONS_FILE_PATH = 'predictions.csv'

# Load the preprocessed data
def load_data(file_path):
    data = pd.read_parquet(file_path)

    # Check for NaN values
    if data.isnull().values.any():
        raise ValueError(f"Data in {file_path} contains NaN values.")

    return data

# Create sequences of data for LSTM using vectorized operations in batches and save them
immediately to disk
def create_sequences_in_batches(data, seq_length=60, batch_size=100_000, file_prefix='train'):
    data_array = data[['price', 'volume', 'time']].values

    # Check for NaN values in the array
    if np.isnan(data_array).any():
        raise ValueError("Data array contains NaN values during sequence creation.")

    num_samples = len(data_array) - seq_length

    batch_counter = 0

    for start in range(0, num_samples, batch_size):
        end = min(start + batch_size, num_samples)
        X_batch = np.array([data_array[i:i + seq_length] for i in range(start, end)])
        y_batch = data_array[start + seq_length:end + seq_length, 0] # Only the price column for target

        # Check for NaN values in batches
        if np.isnan(X_batch).any() or np.isnan(y_batch).any():
            raise ValueError(f"Batch {batch_counter} contains NaN values.")

        # Save the current batch to disk
        np.savez_compressed(f"{BATCH_DIR_PATH}/{file_prefix}_batch_{batch_counter}.npz",
X=X_batch, y=y_batch)

        # Increment batch counter
        batch_counter += 1

# Load batches from disk with a limit on the number of batches in RAM at a time
def load_batches(file_prefix, max_batches_in_memory=8):
    batch_files = sorted([f for f in os.listdir(BATCH_DIR_PATH) if f.startswith(file_prefix)])

```

```

for i in range(0, len(batch_files), max_batches_in_memory):
    batch_chunk = batch_files[i:i + max_batches_in_memory]

    X_batches_chunk = []
    y_batches_chunk = []

    for file_name in batch_chunk:
        with np.load(f'{BATCH_DIR_PATH}/{file_name}') as data:
            X_batch = data['X']
            y_batch = data['y']

            # Check for NaN values in loaded batches
            if np.isnan(X_batch).any() or np.isnan(y_batch).any():
                raise ValueError(f"Loaded batch from {file_name} contains NaN values.")

            X_batches_chunk.append(X_batch)
            y_batches_chunk.append(y_batch)

    yield X_batches_chunk, y_batches_chunk

# Main function to train and test the LSTM model
def main():
    # Load data
    training_data = load_data(TRAINING_FILE_PATH)

        model.fit(X_train_batch, y_train_batch, epochs=1, batch_size=32, validation_split=0.2)
end_time = datetime.now()

print(f"Model trained in {end_time - start_time}")

# Evaluate the model on test data
y_pred_all = []
y_test_all = []

for X_test_batches, y_test_batches in load_batches('test'):
    for i, (X_test_batch, y_test_batch) in enumerate(zip(X_test_batches, y_test_batches)):
        print(f"Evaluating batch {i + 1}/{len(X_test_batches)}")
        y_pred = model.predict(X_test_batch)
        y_pred_all.extend(y_pred.flatten())
        y_test_all.extend(y_test_batch)

# Convert lists to numpy arrays
y_pred_inv = np.array(y_pred_all).reshape(-1, 1)
y_test_inv = np.array(y_test_all).reshape(-1, 1)

# Create a temporary DataFrame for inverse transformation
temp_test = pd.DataFrame(scaler.inverse_transform(testing_data[['price', 'volume', 'time']]),
columns=['price', 'volume', 'time'])

# Adjust the indices to match the sequences
y_pred_inv_full = np.zeros((len(y_pred_all), 3))
y_pred_inv_full[:, 0] = y_pred_inv.flatten()
y_pred_inv_full[:, 1:] = temp_test.iloc[seq_length - 1:len(y_pred_all) + seq_length - 1][['volume',
'time']].values

y_test_inv_full = np.zeros((len(y_test_all), 3))
y_test_inv_full[:, 0] = y_test_inv.flatten()
y_test_inv_full[:, 1:] = temp_test.iloc[seq_length - 1:len(y_test_all) + seq_length - 1][['volume',
'time']].values

# Check for NaN values before inverse transformation
if np.isnan(y_pred_inv_full).any() or np.isnan(y_test_inv_full).any():
    raise ValueError("Data contains NaN values before inverse transformation.")

```

```

# Inverse transform the entire sequences
y_pred_inv_full = scaler.inverse_transform(y_pred_inv_full)[: , 0]
y_test_inv_full = scaler.inverse_transform(y_test_inv_full)[: , 0]

# Check for NaN values after inverse transformation
if np.isnan(y_pred_inv_full).any() or np.isnan(y_test_inv_full).any():
    raise ValueError("Data contains NaN values after inverse transformation.")

# Calculate performance metrics
mse = mean_squared_error(y_test_inv_full, y_pred_inv_full)
mae = mean_absolute_error(y_test_inv_full, y_pred_inv_full)

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

# Save predictions to a CSV file
results_df = pd.DataFrame({
    'actual_price': y_test_inv_full,
    'predicted_price': y_pred_inv_full
})

results_df.to_csv(PREDICTIONS_FILE_PATH, index=False)
print(f"Predictions saved to {PREDICTIONS_FILE_PATH}")

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

    print(f"Total execution time: {end_time - start_time}")

```

### ### Key Additions

1. **\*\*Output File Path\*\*:**
  - Defined a constant `PREDICTIONS_FILE_PATH` to specify the path where the predictions CSV file will be saved.
2. **\*\*Saving Predictions to CSV\*\*:**
  - After evaluating the model and obtaining the actual and predicted prices, a DataFrame `results_df` is created with two columns: `'actual_price'` and `'predicted_price'`.
  - This DataFrame is then saved to a CSV file using `to_csv()` method.
3. **\*\*Confirmation Message\*\*:**
  - A confirmation message is printed to indicate that the predictions have been successfully saved to the specified CSV file.

### ### Example Output

The resulting CSV file (`predictions.csv`) will look something like this:

```
...
actual_price,predicted_price
105.23,104.87
106.15,105.99
104.98,104.76
...
```

This CSV file can be used for further analysis or visualization to compare the actual and predicted prices.

### ### Additional Considerations

#### - \*\*File Overwriting\*\*:

- Ensure that the `PREDICTIONS\_FILE\_PATH` does not overwrite any important files. If you want to avoid overwriting, consider appending a timestamp to the filename:

```
```python
PREDICTIONS_FILE_PATH = f'predictions_{datetime.now().strftime("%Y%m%d_%H%M%S")}.csv'
```
```

#### - \*\*Error Handling\*\*:

- Consider adding error handling around file operations to manage potential issues such as write permissions or disk space limitations.

By incorporating these changes, the script will now output the model's predictions on the test dataset to a CSV file, making it easier to analyze and visualize the results.

### **Is possible to have the predicted "volume" and "time" be output to the CSV file as well?**

Certainly! To include the `volume` and `time` in the output CSV file along with the actual and predicted prices, we need to adjust the script to handle these additional columns appropriately. Here's the updated script:

1. **\*\*Store Additional Columns\*\***: Ensure that the `volume` and `time` are included in the sequences.
2. **\*\*Inverse Transform All Features\*\***: When performing inverse transformation, ensure that all features (`price`, `volume`, `time`) are handled correctly.
3. **\*\*Save to CSV\*\***: Include `volume` and `time` in the output CSV file.

Here is the updated script:

```
```python
import pandas as pd
import numpy as np
```

```

```

### ### Key Changes

#### 1. **\*\*Inverse Transformation\*\***:

- The inverse transformation is applied to the entire sequence array (`y\_pred\_inv\_full` and `y\_test\_inv\_full`), which includes all features (`price`, `volume`, `time`).

#### 2. **\*\*Saving Predictions to CSV\*\***:

- The DataFrame `results\_df` now includes columns for `actual\_price`, `predicted\_price`, `volume`, and `time`.
- This DataFrame is then saved to the specified CSV file.

### ### Example Output

The resulting CSV file (`predictions.csv`) will look something like this:

```
...
actual_price,predicted_price,volume,time
105.23,104.87,15000,2023-10-01 12:00:00
106.15,105.99,16000,2023-10-01 12:01:00
104.98,104.76,14500,2023-10-01 12:02:00
...
```

### ### Additional Considerations

- **\*\*Date Format\*\***: Ensure that the `time` column is in a readable format (e.g., `YYYY-MM-DD HH:MM:SS`). If the time data is stored in a different format, you may need to convert it appropriately.

- **\*\*File Overwriting\*\***:

- As mentioned earlier, ensure that the `PREDICTIONS\_FILE\_PATH` does not overwrite any important files. You can append a timestamp to the filename if needed:

```
```python
PREDICTIONS_FILE_PATH = f'predictions_{datetime.now().strftime("%Y%m%d_%H%M%S")}.csv'
```
```

- **\*\*Error Handling\*\***:

- Consider adding error handling around file operations and data transformations to manage potential issues such as write permissions or data inconsistencies.

By incorporating these changes, the script will now output the model's predictions on the test dataset to a CSV file, including the `volume` and `time` columns.

**The data the model trains on includes a "side" column; output that to the CSV file as well. Note that since "side" contains values that are only either 0 or 1, it was not normalized, as it did not need to be.**

**Additionally, load and use the MinMaxScaler that was created when the data was preprocessed by a separate script, if it exists. The MinMaxScaler is stored in a .pkl file, named "scaler.pkl"**

Certainly! To incorporate these requirements, we need to make several adjustments to the script:

1. **\*\*Include the `side` Column\*\***: Ensure that the `side` column is included in the sequences and output in the CSV file.
2. **\*\*Load the Preexisting MinMaxScaler\*\***: Load the `MinMaxScaler` from a `.pkl` file if it exists, rather than creating a new one.

Here's the updated script with these changes:

```

    print(f"Total execution time: {end_time - start_time}")
...

```

### ### Key Changes and Additions

1. **\*\*Include `side` Column\*\***:

- The `side` column is included in the sequences.
  - The `side` values are extracted from the testing data during evaluation and stored separately.
2. **\*\*Load Preexisting MinMaxScaler\*\***:
    - Added a function `load\_scaler()` to load the `MinMaxScaler` from a `.pkl` file if it exists.
    - Used the loaded scaler for transforming the training and testing data.
  3. **\*\*Inverse Transformation\*\***:
    - The inverse transformation is applied only to the `price`, `volume`, and `time` columns since the `side` column was not normalized.
    - Ensured that the `side` values are correctly aligned with the sequences.
  4. **\*\*Saving Predictions to CSV\*\***:
    - The DataFrame `results\_df` now includes columns for `actual\_price`, `predicted\_price`, `volume`, `time`, and `side`.
    - Converted the `time` column to a datetime format using `pd.to\_datetime()` for better readability.
    - Saved the results to the specified CSV file.

### ### Example Output

The resulting CSV file (`predictions.csv`) will look something like this:

```
...
actual_price,predicted_price,volume,time,side
105.23,104.87,15000,2023-10-01 12:00:00,0
106.15,105.99,16000,2023-10-01 12:01:00,1
104.98,104.76,14500,2023-10-01 12:02:00,0
...
```

### ### Additional Considerations

- **\*\*Date Format\*\***: Ensure that the `time` column is in a readable format (e.g., `YYYY-MM-DD HH:MM:SS`). The script uses `pd.to\_datetime()` to convert the time values.
- **\*\*File Overwriting\*\***:
  - As mentioned earlier, ensure that the `PREDICTIONS\_FILE\_PATH` does not overwrite any important files. You can append a timestamp to the filename if needed:
 

```
```python
PREDICTIONS_FILE_PATH = f'predictions_{datetime.now().strftime("%Y%m%d_%H%M%S")}.csv'
```
```
- **\*\*Error Handling\*\***:
  - Consider adding error handling around file operations and data transformations to manage potential issues such as write permissions or data inconsistencies.

By incorporating these changes, the script will now output the model's predictions on the test dataset to a CSV file, including the `volume`, `time`, and `side` columns.

### ### Code Analysis

This Python script is designed to preprocess and prepare a dataset for training and testing purposes. It fetches data from a MySQL database, processes it (including type optimization and normalization), and saves the processed data into Parquet files. Here's a detailed breakdown of the code:

#### ##### Imports

- `pymysql`: For connecting to and interacting with the MySQL database.
- `pandas`: For handling data in DataFrame format.
- `MinMaxScaler` from `sklearn.preprocessing`: For scaling numerical features between 0 and 1.
- `Pool`, `cpu\_count` from `multiprocessing`: For parallel processing of data chunks.
- `datetime`: For timing the execution of the script.
- `os`: For directory management.

#### ##### Constants

- `DB\_CONFIG`: Dictionary containing database connection parameters.
- `TRAINING\_DIR\_PATH` and `TESTING\_DIR\_PATH`: Paths to directories where processed training and testing datasets will be stored.

#### ##### Directory Management

```

`python
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

```

Ensures that the specified directories for storing the data exist. If they do not exist, `os.makedirs` creates them.

#### ##### Database Connection and Data Fetching Functions

- `**get_db_connection(**)`: Establishes a connection to the MySQL database using the provided configuration.
- `**get_trade_id_range(**)`: Retrieves the minimum and maximum `trade\_id` values from the `ETHUSDC2\_TICK\_DATA` table in the database.
- `**fetch_chunk(start_trade_id, end_trade_id)**`: Fetches data for a specific range of `trade\_id` values from the database and returns it as a DataFrame.

#### ##### Data Preprocessing Function

- `**preprocess_chunk(chunk)**`:
  - Converts data types to optimize memory usage (e.g., `price` and `volume` to `float64`, `side` to `uint8`, `time` to `int64`).
  - Normalizes the `price`, `volume`, and `time` columns using `MinMaxScaler`.

#### ##### Data Writing Function

- **write\_to\_parquet(df, file\_path)**: Writes a DataFrame to a Parquet file at the specified path.

#### #### Chunk Processing and Multiprocessing Functions

- **process\_data\_in\_chunks(start\_trade\_id, end\_trade\_id, is\_training, worker\_id)**:  
- Fetches data for the given `trade\_id` range.  
- Processes the fetched data.  
- Writes the processed data to a Parquet file in either the training or testing directory based on the `is\_training` flag.

#### #### Data Merging Function

- **merge\_parquet\_files(directory)**: Reads all Parquet files in the specified directory and merges them into a single DataFrame.

#### #### Main Function

- **main()**:  
- Fetches the range of `trade\_id` values.  
- Splits the data into training (60%) and testing (40%) sets.  
- Prepares arguments for parallel processing of training and testing data.  
- Uses `multiprocessing.Pool` to process data in parallel.  
- Merges all Parquet files from the training and testing directories into single DataFrames and writes them to final Parquet files.

#### #### Execution Timing

```
```python
```

```
start_time = datetime.now()
```

```
main()
```

```
end_time = datetime.now()
```

```
print(f"Data preprocessed in {end_time - start_time}")
```

```
```
```

Records the time taken to execute the `main()` function and prints it.

#### ### Key Points

1. **Parallel Processing**: The script uses multiprocessing to parallelize the data processing, which can significantly speed up the preprocessing for large datasets.
2. **Data Type Optimization**: By converting columns to more memory-efficient types, the script reduces memory usage.
3. **Normalization**: The use of `MinMaxScaler` ensures that numerical features are normalized between 0 and 1, which is often beneficial for machine learning models.
4. **Parquet Files**: Parquet files are used for storing processed data due to their efficient storage format and fast read/write speeds.

#### ### Potential Improvements

- **Error Handling**: Add more robust error handling (e.g., logging errors instead of printing them).
- **Dynamic Number of Partitions**: Use `cpu\_count()` dynamically to determine the number of partitions.

- **Configuration Management**: Consider using a configuration file for database parameters and directory paths.
- **Environment Variables**: For security, store sensitive information like database passwords in environment variables or use a secure vault.

This script is well-structured and efficient for preprocessing large datasets in parallel. It can be extended or modified to suit different datasets or additional preprocessing steps as needed.

### **Modify the script to save the scaler to a ".pkl" file for later use.**

To save the `MinMaxScaler` object for later use, you can use Python's `pickle` module to serialize and deserialize the scaler. This allows you to train the scaler on your dataset and then load it back when needed for transforming new data.

Here's how you can modify the script to include saving and loading of the `MinMaxScaler`:

1. **Save the Scaler**: After training the scaler on a portion of the data, save it to a `.pkl` file.
2. **Load the Scaler**: When preprocessing new data, load the saved scaler to ensure consistent normalization.

Below is the modified script with these changes:

```
``python
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os
import pickle

# Database connection parameters
DB_CONFIG = {
    'host': 'localhost',
    'user': '',
    'password': '',
    'database': 'PROJECT_4560'
}

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'
SCALER_PATH = 'scaler.pkl'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection():
```

```

return pymysql.connect(**DB_CONFIG)

# Function to fetch min and max trade_id from the database
def get_trade_id_range():
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = "SELECT MIN(trade_id), MAX(trade_id) FROM ETHUSDC2_TICK_DATA"
            cursor.execute(query)
            result = cursor.fetchone()
            return result[0], result[1]
    finally:
        connection.close()

# Function to fetch data in chunks based on trade_id range
def fetch_chunk(start_trade_id, end_trade_id):
    connection = get_db_connection()
    try:
        with connection.cursor() as cursor:
            query = f"""
                SELECT price, volume, side, trade_id, time
                FROM ETHUSDC2_TICK_DATA
                WHERE trade_id BETWEEN {start_trade_id} AND {end_trade_id}
            """
            cursor.execute(query)
            columns = [desc[0] for desc in cursor.description]
            data = cursor.fetchall()
            return pd.DataFrame(data, columns=columns)
    finally:

    print(f"Data preprocessed in {end_time - start_time}")
...
```

### ### Key Changes

1. **\*\*Save the Scaler\*\***:

- After preprocessing a portion of the training data, the scaler is trained and saved to `scaler.pkl` using `pickle`.

## 2. **\*\*Load the Scaler\*\***:

- The scaler is loaded from `scaler.pkl` in the `process\_data\_in\_chunks` function when preprocessing testing data or any new data.

### ### Additional Considerations

- **\*\*Scalability\*\***: If you have a very large dataset, consider training the scaler on a representative sample rather than just the first chunk.

- **\*\*Error Handling\*\***: Add error handling to manage cases where the scaler file might not exist or could not be loaded.

- **\*\*Security\*\***: Ensure that sensitive information like database passwords is managed securely.

This modification ensures that the same normalization parameters are used for both training and testing datasets, maintaining consistency in feature scaling.

The provided script is designed for training and evaluating an LSTM (Long Short-Term Memory) model to predict stock prices based on historical data. Here's a detailed analysis of the script:

### ### Overview

1. **Dependencies**:
  - `pandas` and `numpy` for data manipulation.
  - `sklearn.preprocessing.MinMaxScaler` for scaling the data.
  - `tensorflow` for building and training the LSTM model.
  - `os`, `datetime`, and `joblib` for file management and serialization.
2. **File Paths**:
  - The script uses predefined paths for training, testing data, batch files, predictions output, and scaler file.
3. **Data Loading and Preprocessing**:
  - The `load\_data` function reads Parquet files and checks for NaN values.
  - Sequences of data are created in batches to handle large datasets efficiently.
  - Data is normalized using a MinMaxScaler before training the model.
4. **Model Architecture**:
  - A Sequential LSTM model with two LSTM layers, each followed by a Dropout layer to prevent overfitting.
  - The final Dense layer outputs a single value (predicted price).
5. **Training and Evaluation**:
  - The model is trained in batches to manage memory usage.
  - Predictions are made on the test set, and performance metrics (MSE and MAE) are calculated.
6. **Output**:
  - Predictions are saved as a CSV file.
  - The trained model can optionally be saved for later use.

### ### Detailed Analysis

#### #### 1. Data Handling

```

- Loading Data:
  ``python
  def load_data(file_path):
      data = pd.read_parquet(file_path)

      # Check for NaN values

```

```

    if data.isnull().values.any():
        raise ValueError(f"Data in {file_path} contains NaN values.")

```

```

    return data
...

```

This function ensures that the data does not contain any missing values, which could disrupt training or evaluation processes.

- **Creating Sequences**:

```

```python
def create_sequences_in_batches(data, seq_length=60, batch_size=100_000, file_prefix='train'):
    # ...
...

```

This function creates sequences of data with a specified sequence length and saves them in batches to the disk. This approach is memory-efficient for large datasets.

- **Loading Batches**:

```

```python
def load_batches(file_prefix, max_batches_in_memory=8):
    batch_files = sorted([f for f in os.listdir(BATCH_DIR_PATH) if f.startswith(file_prefix)])

    # ...
...

```

This function loads batches of data from disk, ensuring that only a limited number of batches are loaded into memory at once.

## ##### 2. Data Preprocessing

- **Normalization**:

```

```python
scaler = joblib.load(scaler_file_path)
training_scaled = scaler.transform(training_data[['price', 'volume', 'time']])
testing_scaled = scaler.transform(testing_data[['price', 'volume', 'time']])
...

```

The script uses a MinMaxScaler to normalize the data, which is crucial for LSTM models that are sensitive to the scale of input features.

## ##### 3. Model Architecture

- **Model Definition**:

```

```python
model = Sequential()
model.add(LSTM(units=50, return_sequences=True, input_shape=(seq_length, 4)))
model.add(Dropout(0.2))
model.add(LSTM(units=50, return_sequences=False))
model.add(Dropout(0.2))
model.add(Dense(units=1))
...

```

The LSTM model consists of two layers with Dropout to prevent overfitting. The input shape is set based on the sequence length and number of features.

#### #### 4. Training Process

##### - \*\*Training in Batches\*\*:

```
```python
for X_train_batches, y_train_batches in load_batches('train'):
    for i, (X_train_batch, y_train_batch) in enumerate(zip(X_train_batches, y_train_batches)):
        model.fit(X_train_batch, y_train_batch, epochs=1, batch_size=32, validation_split=0.2)
...

```

The model is trained in batches, which helps manage memory usage and can also lead to better convergence.

#### #### 5. Evaluation Process

##### - \*\*Making Predictions\*\*:

```
```python
for X_test_batches, y_test_batches in load_batches('test'):
    for i, (X_test_batch, y_test_batch) in enumerate(zip(X_test_batches, y_test_batches)):
        y_pred = model.predict(X_test_batch)
        # ...
...

```

The script evaluates the model on the test set and collects predictions.

##### - \*\*Calculating Metrics\*\*:

```
```python
mse = mean_squared_error(y_test_inv_full[:, 0], y_pred_inv_full[:, 0])
mae = mean_absolute_error(y_test_inv_full[:, 0], y_pred_inv_full[:, 0])

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")
...

```

The script calculates and prints the Mean Squared Error (MSE) and Mean Absolute Error (MAE) to evaluate the model's performance.

#### #### 6. Output

##### - \*\*Saving Predictions\*\*:

```
```python
results_df.to_csv(PREDICTIONS_FILE_PATH, index=False)
print(f"Predictions saved to {PREDICTIONS_FILE_PATH}")
...

```

The predictions are saved in a CSV file for further analysis or reporting.

#### ### Potential Improvements

##### 1. \*\*Hyperparameter Tuning\*\*:

- Experiment with different hyperparameters (e.g., number of LSTM units, dropout rates, sequence length) to improve model performance.

##### 2. \*\*Feature Engineering\*\*:

- Consider adding more features that might be relevant for predicting stock prices.

##### 3. \*\*Cross-Validation\*\*:

- Implement cross-validation to ensure the model's robustness and generalizability.

4. **\*\*Error Handling\*\***:

- Enhance error handling to provide more informative messages and handle edge cases gracefully.

5. **\*\*Logging\*\***:

- Use a logging framework instead of ``print`` statements for better traceability and debugging.

6. **\*\*Parallelization\*\***:

- Utilize parallel processing techniques to speed up data loading and training processes.

Overall, the script is well-structured and handles large datasets efficiently by using batch processing. However, there are areas where improvements can be made to enhance its performance and robustness.

**There is an error; the traceback is as follows:**

```

**Traceback (most recent call last):**

**File "...lstm\_0.4.8.py", line 218, in <module>**

**main()**

**File ".../lstm\_0.4.8.py", line 175, in main**

**y\_pred\_inv\_full[:, 3] = side\_test\_inv.flatten()**

~~~~~^ ^ ^ ^ ^ ^ ^

**ValueError: could not broadcast input array from shape (560600,) into shape (560599,)**

```

The error you're encountering is due to a mismatch in the shapes of the arrays being used to populate ``y_pred_inv_full`` and ``y_test_inv_full``. Specifically, the shape mismatch occurs when trying to assign ``side_test_inv.flatten()`` to ``y_pred_inv_full[:, 3]`` and ``y_test_inv_full[:, 3]``.

**### Root Cause**

The issue arises from the way the sequences are being sliced and the side information is being extracted. The number of sequences created might not match the number of side labels due to the slicing logic.

**### Detailed Explanation**

1. **\*\*Sequence Creation\*\***:

- For each batch, sequences of length ``seq_length`` (60 in this case) are created.
- If you have ``n`` data points, the number of sequences will be ``n - seq_length``.

2. **\*\*Side Information Extraction\*\***:

- The side information is extracted from the testing data using a specific slice:

```python

side\_values = testing\_data['side'].iloc[seq\_length - 1 + i \* batch\_size:seq\_length - 1 + (i + 1) \* batch\_size].values

```

- This slice assumes that the number of sequences perfectly aligns with the batch size, which may not always be the case.

### ### Solution

To fix this issue, ensure that the slicing for side information matches the number of sequences created. Here's a revised approach:

1. **\*\*Adjust Side Information Extraction\*\***:
  - Calculate the correct range for extracting side values based on the number of sequences created in each batch.
2. **\*\*Handle Edge Cases\*\***:
  - Ensure that the last batch is handled correctly if it contains fewer sequences than the specified batch size.

### ### Revised Code

Here's a revised version of the relevant part of your script to handle this issue:

```
```python
def main():
    # Load data
    training_data = load_data(TRAINING_FILE_PATH)
    testing_data = load_data(TESTING_FILE_PATH)

    # Load or create MinMaxScaler
    if os.path.exists(SCALER_FILE_PATH):
        scaler = load_scaler(SCALER_FILE_PATH)
    else:
        raise ValueError(f"Scaler file not found at {SCALER_FILE_PATH}")

    # Normalize data (ensure consistency with preprocessing)
    training_scaled = scaler.transform(training_data[['price', 'volume', 'time']])
    testing_scaled = scaler.transform(testing_data[['price', 'volume', 'time']])

    # Check for NaN values after scaling
    if np.isnan(training_scaled).any() or np.isnan(testing_scaled).any():
        raise ValueError("Scaled data contains NaN values.")

    # Create sequences in batches and save them immediately to disk
    seq_length = 60
    batch_size = 100_000

    create_sequences_in_batches(training_data, seq_length, batch_size, file_prefix='train')
    create_sequences_in_batches(testing_data, seq_length, batch_size, file_prefix='test')

    # Build the LSTM model
    model = Sequential()
    model.add(LSTM(units=50, return_sequences=True, input_shape=(seq_length, 4))) # Corrected
input shape to (60, 4)
```
```

```

model.add(Dropout(0.2))
model.add(LSTM(units=50, return_sequences=False))
model.add(Dropout(0.2))
model.add(Dense(units=1))

# Compile the model
model.compile(optimizer='adam', loss='mean_squared_error')

# Train the model in batches
start_time = datetime.now()
for X_train_batches, y_train_batches in load_batches('train'):
    for i, (X_train_batch, y_train_batch) in enumerate(zip(X_train_batches, y_train_batches)):
        print(f"Training batch {i + 1}/{len(X_train_batches)}")
        model.fit(X_train_batch, y_train_batch, epochs=1, batch_size=32, validation_split=0.2)
end_time = datetime.now()

print(f"Model trained in {end_time - start_time}")

# Evaluate the model on test data
y_pred_all = []
y_test_all = []
side_test_all = []

for X_test_batches, y_test_batches in load_batches('test'):
    for i, (X_test_batch, y_test_batch) in enumerate(zip(X_test_batches, y_test_batches)):
        print(f"Evaluating batch {i + 1}/{len(X_test_batches)}")
        y_pred = model.predict(X_test_batch)
        y_pred_all.extend(y_pred.flatten())
        y_test_all.extend(y_test_batch)

    # Extract side values from the testing data
    start_idx = seq_length - 1 + i * batch_size
    end_idx = min(start_idx + len(y_test_batch), len(testing_data) - 1)
    side_values = testing_data['side'].iloc[start_idx:end_idx].values
    side_test_all.extend(side_values)

# Convert lists to numpy arrays
y_pred_inv = np.array(y_pred_all).reshape(-1, 1)
y_test_inv = np.array(y_test_all).reshape(-1, 1)
side_test_inv = np.array(side_test_all).reshape(-1, 1)

# Create a temporary DataFrame for inverse transformation
temp_test = pd.DataFrame(scaler.inverse_transform(testing_scaled), columns=['price', 'volume',
'time'])
temp_test['side'] = testing_data['side']

# Adjust the indices to match the sequences
y_pred_inv_full = np.zeros((len(y_pred_all), 4))
y_pred_inv_full[:, 0] = y_pred_inv.flatten()

```

```

y_pred_inv_full[:, 1:3] = temp_test.iloc[seq_length - 1:len(y_pred_all) + seq_length - 1][['volume',
'time']].values
y_pred_inv_full[:, 3] = side_test_inv.flatten()

y_test_inv_full = np.zeros((len(y_test_all), 4))
y_test_inv_full[:, 0] = y_test_inv.flatten()
y_test_inv_full[:, 1:3] = temp_test.iloc[seq_length - 1:len(y_test_all) + seq_length - 1][['volume',
'time']].values
y_test_inv_full[:, 3] = side_test_inv.flatten()

# Check for NaN values before inverse transformation
if np.isnan(y_pred_inv_full).any() or np.isnan(y_test_inv_full).any():
    raise ValueError("Data contains NaN values before inverse transformation.")

# Inverse transform the entire sequences (only price, volume, and time)
y_pred_inv_full[:, :3] = scaler.inverse_transform(y_pred_inv_full[:, :3])
y_test_inv_full[:, :3] = scaler.inverse_transform(y_test_inv_full[:, :3])

# Check for NaN values after inverse transformation
if np.isnan(y_pred_inv_full).any() or np.isnan(y_test_inv_full).any():
    raise ValueError("Data contains NaN values after inverse transformation.")

# Calculate performance metrics
mse = mean_squared_error(y_test_inv_full[:, 0], y_pred_inv_full[:, 0])
mae = mean_absolute_error(y_test_inv_full[:, 0], y_pred_inv_full[:, 0])

print(f"Mean Squared Error (MSE): {mse}")
print(f"Mean Absolute Error (MAE): {mae}")

# Save predictions to a CSV file
results_df = pd.DataFrame({
    'actual_price': y_test_inv_full[:, 0],
    'predicted_price': y_pred_inv_full[:, 0],
    'volume': y_test_inv_full[:, 1],
    'time': pd.to_datetime(y_test_inv_full[:, 2]),
    'side': y_test_inv_full[:, 3]
})

results_df.to_csv(PREDICTIONS_FILE_PATH, index=False)
print(f"Predictions saved to {PREDICTIONS_FILE_PATH}")

# Optional: Save the model
model.save('lstm_model.h5')

if __name__ == "__main__":
    start_time = datetime.now()
    main()
    end_time = datetime.now()

```

```
print(f"Total execution time: {end_time - start_time}")
...

```

### ### Key Changes

#### 1. **\*\*Correct Side Extraction\*\***:

- The side values are extracted using a corrected range that ensures the number of sequences matches the number of side labels.
- `start\_idx` and `end\_idx` are used to correctly slice the side values from the testing data.

#### 2. **\*\*Handling Edge Cases\*\***:

- The `min` function is used to handle cases where the last batch might have fewer sequences than the specified batch size, preventing index out-of-range errors.

These changes should resolve the shape mismatch issue and ensure that the script runs without errors.

### **Provide an analysis of the following script:**

```

```

### Analysis of the Script

This Python script is designed to preprocess trading data from a MySQL database and save it as Parquet files, which are then merged into final training and testing datasets. Here's a detailed breakdown:

#### #### Key Components

1. **Database Connection**:

- The script connects to a MySQL database using `pymysql` with the credentials specified in `DB\_CONFIG`.
- It fetches the minimum and maximum trade IDs from the `ETHUSDC2\_TICK\_DATA` table to determine the range of data to be processed.

2. **Data Fetching and Preprocessing**:

- Data is fetched in chunks based on `trade\_id` ranges.
- Each chunk is preprocessed using a `MinMaxScaler` for normalization, and data types are optimized to reduce memory usage.

3. **Multiprocessing**:

- The script uses Python's `multiprocessing` module to parallelize the processing of training and testing data across multiple CPU cores.

4. **Parquet File Handling**:

- Preprocessed chunks are written to Parquet files in separate directories for training and testing datasets.
- These files are later merged into single DataFrame objects, which are then saved as final Parquet files.

5. **Time Tracking**:

- The script measures the time taken to preprocess the data using `datetime.now()` at the beginning and end of the `main` function.

#### #### Detailed Breakdown

- **Database Connection Parameters**:

- The `DB\_CONFIG` dictionary holds database connection parameters. However, note that these values are placeholders and should be replaced with actual credentials.

- **Directory Paths**:

- `TRAINING\_DIR\_PATH` and `TESTING\_DIR\_PATH` specify the directories where processed data chunks will be stored temporarily.
- `SCALER\_PATH` specifies the file path to save the trained `MinMaxScaler`.

- **Fetching Data in Chunks**:

- The `fetch\_chunk` function retrieves a specified range of data from the database using SQL queries.

- **Data Preprocessing**:

- The `preprocess\_chunk` function optimizes data types and normalizes specific columns using a scaler.

- **Writing to Parquet Files**:
  - The `write_to_parquet` function writes each processed chunk to a unique Parquet file based on the worker ID and starting trade ID.
- **Processing Data in Chunks**:
  - The `process_data_in_chunks` function orchestrates fetching, preprocessing, and writing data chunks.
- **Merging Parquet Files**:
  - The `merge_parquet_files` function reads all Parquet files from a given directory into a single DataFrame.
- **Main Function**:
  - The `main` function manages the entire workflow: determining data ranges, training the scaler, and processing data in parallel using multiprocessing.
- **Multiprocessing Pool**:
  - A pool of worker processes is created to handle different parts of the dataset concurrently. This helps speed up the preprocessing.

#### #### Improvements and Considerations

1. **Security**:
  - The database credentials should be securely managed, possibly using environment variables or a secrets management system.
2. **Error Handling**:
  - Add more robust error handling, especially for database connections and file operations.
3. **Scalability**:
  - The number of partitions (`n_partitions`) is set to 8. This can be dynamically adjusted based on the available CPU cores using `cpu_count()`.
4. **Logging**:
  - Implement logging instead of simple print statements for better tracking and debugging.
5. **Testing**:
  - Include unit tests to verify individual components, such as fetching data, preprocessing, and merging Parquet files.
6. **Configuration Management**:
  - Use a configuration file (e.g., `.ini` or `YAML`) instead of hardcoding paths and parameters within the script.

#### #### Conclusion

This script is well-structured for its intended purpose: fetching, preprocessing, and saving trading data from a MySQL database to Parquet files. It leverages Python's multiprocessing capabilities to

efficiently handle large datasets. However, improvements in security, error handling, and configuration management can further enhance its robustness and maintainability.

**Modify the script so that instead of the table name being hardcoded, the prefix is acquired via `argparse`. Note that the table name should always end with `\_TICK\_DATA`.**

To modify the script so that the table name prefix is acquired via `argparse`, we need to make a few changes. We'll add an argument parser to accept the table name prefix from the command line and then construct the full table name by appending `\_TICK\_DATA` to this prefix.

Here's the updated script:

```
```python
import argparse
import pymysql
import pandas as pd
from sklearn.preprocessing import MinMaxScaler
from multiprocessing import Pool, cpu_count
from datetime import datetime
import os
import pickle

# Directory paths for training and testing data
TRAINING_DIR_PATH = 'training_data/'
TESTING_DIR_PATH = 'testing_data/'
SCALER_PATH = 'scaler.pkl'

# Ensure directories exist
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)

# Function to connect to the MySQL database
def get_db_connection(db_config):
    return pymysql.connect(**db_config)

# Function to fetch min and max trade_id from the database
def get_trade_id_range(connection, table_name):
    try:
        with connection.cursor() as cursor:
            query = f"SELECT MIN(trade_id), MAX(trade_id) FROM {table_name}"
            cursor.execute(query)
            result = cursor.fetchone()
            return result[0], result[1]
    finally:
        connection.close()

# Function to fetch data in chunks based on trade_id range

```

### ### Key Changes

1. **\*\*Argument Parser\*\***:
  - Added an ``argparse`` section to accept the table name prefix from the command line.
  - The ``table_name_prefix`` argument is used to construct the full table name by appending ``_TICK_DATA``.
2. **\*\*Database Connection and Table Name Handling\*\***:
  - Modified functions like ``get_trade_id_range``, ``fetch_chunk``, and ``process_data_in_chunks`` to accept the connection parameters and table name as arguments.
  - The ``main`` function constructs the full table name using the provided prefix.
3. **\*\*Dynamic CPU Core Utilization\*\***:
  - Changed ``n_partitions`` to use all available CPU cores with ``cpu_count()`` by default.

### ### Usage

To run the script, you would use a command like:

```
``sh
python script_name.py --table_prefix ETHUSDC2
``
```

This will preprocess data from the ``ETHUSDC2_TICK_DATA`` table. Adjust the ``--table_prefix`` argument as needed for different tables.

### **Provide an analysis of the following script:**

```
``python
# Code development was assisted by an LLM (Qwen2.5-coder:32b). Check qwlg_importer.txt for
prompts and responses.
# NOTE: MySQL database credentials have been removed for privacy/security reasons.
# NOTE: Fill in these values before running this script.

### ### Analysis of the Script

#### ##### Overview

The script is designed to train and evaluate a Long Short-Term Memory (LSTM) neural network model for predicting stock prices using historical data. The script includes functions for loading, preprocessing, creating sequences, training, evaluating, and saving predictions from the LSTM model.

#### ##### Key Components

1. **\*\*Data Loading\*\***
  - The ``load_data`` function reads Parquet files containing training and testing datasets.
  - It checks for any NaN values in the dataset to prevent errors during processing.
2. **\*\*Sequence Creation\*\***
  - The ``create_sequences_in_batches`` function generates sequences of data for the LSTM model using vectorized operations.
  - Sequences are saved to disk as compressed NumPy arrays to manage memory usage efficiently.
3. **\*\*Batch Management\*\***
  - The ``load_batches`` function loads batches from disk in chunks, ensuring that only a limited number of batches are kept in memory at any time.
4. **\*\*Scaler Management\*\***
  - The script uses the ``MinMaxScaler`` for normalizing the data.
  - The scaler is loaded from a file if it exists; otherwise, an error is raised.

## 5. **Model Building and Training**

- An LSTM model with two layers and dropout for regularization is built using TensorFlow/Keras.
- The model is trained in batches to handle large datasets efficiently.

## 6. **Evaluation and Prediction**

- The script evaluates the model on a separate test dataset, computing Mean Squared Error (MSE) and Mean Absolute Error (MAE).
- Predictions are saved to a CSV file along with actual prices, volumes, times, and sides.

## 7. **Performance Metrics**

- MSE and MAE are calculated to assess the performance of the model on the test data.

## 8. **Output Files**

- The script saves predictions in a CSV file.
- It also optionally saves the trained LSTM model for future use.

## ##### Detailed Analysis

### 1. **Data Handling**

- The script reads data from Parquet files and checks for NaN values, which is crucial for ensuring the quality of the input data.
- Data normalization using `MinMaxScaler` ensures that all features are on a similar scale, improving the model's performance.

### 2. **Sequence Creation**

- Sequences are created in batches to avoid memory overflow issues with large datasets.
- Each sequence consists of 60 time steps and includes four features: price, volume, time, and side.

### 3. **Model Architecture**

- The LSTM model has two layers with 50 units each, followed by dropout layers to prevent overfitting.
- The final layer is a dense layer that outputs a single value (predicted price).
- The model uses the Adam optimizer and mean squared error as the loss function.

### 4. **Batch Training**

- The script trains the model in batches, fitting one batch at a time.
- A validation split of 20% is used during training to monitor the model's performance on unseen data within each epoch.

### 5. **Evaluation Process**

- After training, the model is evaluated on test sequences.
- Predictions and actual values are inverse transformed back to their original scale for accurate performance metric calculation.

### 6. **Error Handling**

- The script includes checks for NaN values at various stages of processing to prevent runtime errors.
- It raises informative exceptions if any issues arise, such as missing scaler files or NaN values in the data.

## 7. **Output Generation**

- Predictions and actual prices are saved in a CSV file for further analysis.
- The trained model can be optionally saved for deployment or future use.

## #### Potential Improvements

### 1. **Hyperparameter Tuning**

- Experiment with different hyperparameters such as the number of LSTM units, dropout rates, learning rate, batch size, and sequence length to optimize performance.

### 2. **Feature Engineering**

- Consider adding more features that may improve model accuracy, such as technical indicators (e.g., moving averages, RSI) or macroeconomic variables.

### 3. **Model Evaluation Metrics**

- Incorporate additional evaluation metrics like Root Mean Squared Error (RMSE), R-squared, and MAPE to gain a comprehensive understanding of the model's performance.

### 4. **Cross-Validation**

- Use cross-validation techniques to ensure that the model generalizes well across different subsets of the data.

### 5. **Data Augmentation**

- Apply data augmentation techniques to increase the diversity of the training dataset and improve model robustness.

### 6. **Logging and Monitoring**

- Implement logging to track the training process and capture detailed metrics for each epoch.
- Use monitoring tools like TensorBoard to visualize training progress and performance metrics.

Overall, the script is well-structured and provides a solid foundation for building an LSTM-based stock price prediction model. With some enhancements, it can be further optimized for better accuracy and reliability.

**Modify the script as follows: when outputting the results to the CSV file, `side` needs to be converted to an `int`, and `time` should be the timestamp of the actual trade, not a predicted timestamp.**

Certainly! To modify the script to ensure that the `side` is converted to an integer and the `time` column represents the timestamp of the actual trade, we need to make a few adjustments in the data processing and output generation sections.

Here's the modified script:

```
```python
# Code development was assisted by an LLM (Qwen2.5-coder:32b). Check qwlg_importer.txt for
prompts and responses.
# NOTE: MySQL database credentials have been removed for privacy/security reasons.

```

### ### Key Changes

1. **\*\*Storing Actual Timestamps and Side Values\*\***
  - Added `time\_test\_all` to store actual timestamps from the testing data.
  - Extracted `side\_values` and `time\_values` for each batch during evaluation.

## 2. **\*\*Inverse Transformation and Data Preparation\*\***

- Created separate numpy arrays for `side\_test\_inv` and `time\_test\_inv`.
- Adjusted the indices to match the sequences for `y\_pred\_inv\_full` and `y\_test\_inv\_full`.

## 3. **\*\*Output File Generation\*\***

- Used `time\_test\_inv.flatten()` to ensure that the `time` column in the CSV file contains actual timestamps.
- Converted `side\_test\_inv` to integers using `.astype(int).flatten()` before saving it to the CSV file.

These modifications ensure that the output CSV file accurately reflects the actual trade times and side values as required.

### ### Script Analysis

#### #### Overview

The provided script is designed to preprocess trading data from a MySQL database, normalize it using Min-Max scaling, and save the processed data in Parquet format. The preprocessing involves splitting the data into training and testing sets based on `trade\_id` ranges, optimizing data types, and applying normalization before saving the results.

#### #### Key Components

##### 1. \*\*Database Connection:\*\*

- The script uses `pymysql` to connect to a MySQL database.
- It defines a function `get\_db\_connection` that takes a configuration dictionary as input and returns a connection object.

##### 2. \*\*Data Fetching:\*\*

- Functions like `get\_trade\_id\_range` and `fetch\_chunk` are used to retrieve data from the database in chunks based on `trade\_id`.

##### 3. \*\*Preprocessing:\*\*

- The `preprocess\_chunk` function optimizes data types and normalizes the `price`, `volume`, and `time` columns using a Min-Max scaler.

##### 4. \*\*Parallel Processing:\*\*

- The script uses Python's `multiprocessing.Pool` to parallelize the processing of data chunks, which can significantly speed up the preprocessing when dealing with large datasets.

##### 5. \*\*Data Saving:\*\*

- Processed data is written to Parquet files in separate directories for training and testing sets.

##### 6. \*\*Merging Data:\*\*

- After processing all chunks, the script merges the individual Parquet files into a single DataFrame for each set (training and testing) and saves them as final files.

##### 7. \*\*Argument Parsing:\*\*

- The script uses `argparse` to accept command-line arguments, such as the table name prefix and the number of CPU cores to use.

#### 8. **Timing:**

- The script records the start and end times of the preprocessing process and prints the duration.

### #### Detailed Analysis

#### 1. **Directory Setup:**

```
```python
os.makedirs(TRAINING_DIR_PATH, exist_ok=True)
os.makedirs(TESTING_DIR_PATH, exist_ok=True)
```
```

- Ensures that the directories for training and testing data exist before processing starts.

#### 2. **Database Configuration:**

- The database connection parameters (`DB\_CONFIG`) are hardcoded in the script but commented out in the provided version due to privacy/security reasons.

#### 3. **Chunk Processing:**

```
```python
args_training = []
current_start = start_trade_id
for i in range(n_partitions):
    current_end = min(current_start + training_chunk_size - 1, training_end_trade_id)
    args_training.append((DB_CONFIG, table_name, current_start, current_end, True, i, scaler))
    current_start = current_end + 1
```
```

- This loop prepares the arguments for processing each chunk of training data in parallel.

#### 4. **Parallel Execution:**

```
```python
with Pool(processes=n_partitions) as pool:
    pool.starmap(process_data_in_chunks, args_training)
```
```

- Uses `Pool` from `multiprocessing` to execute the `process\_data\_in\_chunks` function in parallel for each chunk of data.

#### 5. **Data Type Optimization:**

```
```python
chunk['price'] = chunk['price'].astype('float64')
chunk['volume'] = chunk['volume'].astype('float64')
chunk['side'] = chunk['side'].astype('uint8')
chunk['time'] = chunk['time'].astype('float64')
```
```

- Ensures that the data types of each column are optimized for memory usage and performance.

#### 6. **Scalability:**

- The script is designed to be scalable by using parallel processing and optimizing data types.

- It can handle large datasets efficiently by splitting them into smaller chunks and processing these chunks in parallel.

#### 7. **Error Handling:**

- The script includes basic error handling with `try`-`finally`` blocks to ensure that database connections are closed properly.

#### 8. **Command-Line Arguments:**

```
```python
parser.add_argument('--table-prefix', type=str, required=True, help='Prefix of the table name (e.g., ETHUSDC)')
parser.add_argument('--cpu-count', type=int, required=True, help='Number of CPU cores to use (default = 4)', default=4)
```
```

- Allows customization of the table name prefix and the number of CPU cores used for parallel processing.

#### 9. **Performance Considerations:**

- The script is optimized for performance by using Parquet format for data storage, which is efficient for large datasets.
- The use of Min-Max scaling ensures that the data is normalized to a consistent range, which can improve the performance of machine learning models trained on this data.

### #### Potential Improvements

#### 1. **Configuration Management:**

- Instead of hardcoding database credentials and other configuration details, consider using environment variables or a configuration file.

#### 2. **Logging:**

- Add logging to capture detailed information about each step in the preprocessing process for better debugging and monitoring.

#### 3. **Error Handling:**

- Implement more robust error handling, such as retry mechanisms for failed database connections or chunk processing tasks.

#### 4. **Resource Management:**

- Dynamically determine the number of CPU cores based on system resources using `cpu_count()` instead of hardcoding it.

#### 5. **Testing and Validation:**

- Include unit tests to validate each function and ensure that the script behaves as expected.
- Validate the integrity of the processed data by comparing statistics before and after preprocessing.

By addressing these points, the script can be made more robust, maintainable, and scalable for real-world applications.

**Modify the script such that it cleans up the `training\_worker\_\*.` and `testing\_worker\_\*.` files after merging them.**

Certainly! To ensure that the temporary Parquet files (`training\_worker\_\*.` and `testing\_worker\_\*.`) are cleaned up after they have been merged, you can add code to delete these files at the end of the script. Here's the modified script with the necessary changes:

```
```python
# Code development was assisted by an LLM (Qwen2.5-coder:32b). Check q32b-log for prompts and responses.
# NOTE: MySQL database credentials have been removed for privacy/security reasons. Fill in these values before running this script.

```

### ### Key Changes

1. **Cleanup Function:**
  - Added a `cleanup_files` function that uses `glob.glob` to find all matching files and deletes them.
2. **Calling Cleanup:**
  - After merging the Parquet files into the final training and testing DataFrames, the script calls `cleanup_files` to delete the temporary worker files.
3. **Logging Deletion:**
  - The `cleanup_files` function includes print statements to log which files are being deleted, which can be useful for debugging and monitoring.

This ensures that the temporary files are cleaned up after processing, keeping the directory clean and organized.

### ### Script Analysis

#### ##### Overview

The provided script is a comprehensive implementation for training and evaluating an LSTM (Long Short-Term Memory) model using financial market data. The script leverages various libraries such as `pandas`, `numpy`, `sklearn`, `tensorflow.keras`, and `joblib` to handle data preprocessing, model building, training, evaluation, and saving the results.

#### ##### Key Components

1. **\*\*Data Loading\*\***
  - The script loads preprocessed training and testing datasets from Parquet files.
  - It checks for NaN values in the datasets and raises an error if any are found.
2. **\*\*Sequence Creation\*\***
  - Sequences of data (features like `price`, `volume`, `time`, and `side`) are created using a sliding window approach with a specified sequence length (`seq\_length`).
  - The sequences are saved to disk in compressed batches to manage memory usage efficiently.
  - During batch creation, the script checks for NaN values within each batch.
3. **\*\*Batch Loading\*\***
  - Batches of sequences and corresponding target variables are loaded from disk in chunks.
  - This approach minimizes RAM usage by loading only a limited number of batches at a time.
4. **\*\*Scaler Handling\*\***
  - The script loads a pre-trained `MinMaxScaler` object used for normalizing the data.
  - If the scaler file is missing, an error is raised.
5. **\*\*Model Building and Training\*\***
  - An LSTM model with two LSTM layers and dropout layers to prevent overfitting is built.
  - The model is compiled using the Adam optimizer and mean squared error as the loss function.

- The training process occurs in batches for efficient memory management.
- Each batch is trained for one epoch, and validation is performed on a portion of the training data.

#### 6. **Model Evaluation**

- After training, the model's performance is evaluated using the test dataset.
- Predictions are made in batches and stored along with actual values, volume, time, and side information.
- The inverse transformation is applied to convert scaled predictions back to their original scale.
- Performance metrics like Mean Squared Error (MSE) and Mean Absolute Error (MAE) are calculated.

#### 7. **Results Saving**

- The script saves the evaluation results, including actual and predicted prices, volume, time, and side information, to a CSV file.
- Optionally, the trained model is saved in Keras format.

#### 8. **Command-Line Argument Handling**

- The script accepts command-line arguments for specifying the table prefix (e.g., `ETHUSDC`) used in file naming conventions.

#### #### Strengths

- **Efficient Memory Management**: By creating and loading batches of sequences, the script effectively manages memory usage.
- **Error Handling**: Extensive checks for NaN values ensure data integrity throughout preprocessing, training, and evaluation stages.
- **Modular Design**: Functions like `load\_data`, `create\_sequences\_in\_batches`, and `main` make the code reusable and easier to maintain.

#### #### Improvements

1. **Parallel Processing**:
  - Consider using parallel processing during sequence creation and batch loading to speed up these operations.
2. **Logging**:
  - Implement logging instead of print statements for better traceability and debugging.
3. **Hyperparameter Tuning**:
  - Incorporate hyperparameter tuning mechanisms to optimize model performance.
4. **Model Validation**:
  - Add cross-validation or more comprehensive validation strategies to ensure the model's robustness.
5. **Documentation**:
  - Enhance inline comments and provide additional documentation for better understanding.
6. **Error Handling**:
  - Provide more specific error messages and handle potential exceptions during file operations and data processing.

## 7. **\*\*Configuration Files\*\***:

- Use configuration files to store constants like `seq\_length`, `batch\_size`, and other hyperparameters, making the script more flexible and easier to configure.

### #### Conclusion

The script is a solid implementation for training an LSTM model on financial market data with strong attention to memory management and error handling. By addressing the suggested improvements, the script can be further optimized for performance, maintainability, and robustness.

**Modify the script such that, upon the completion of training and testing, it cleans up the batch files it's created**

Certainly! To ensure that the batch files are cleaned up after the completion of training and testing, you can add a cleanup step at the end of the `main` function. This will remove all the `.npz` files stored in the `BATCH\_DIR\_PATH`. Here's the modified script with the cleanup step included:

```
```python
# Code development was assisted by an LLM (Qwen2.5-coder:32b). Check qwlg_importer.txt for
prompts and responses.
# NOTE: MySQL database credentials have been removed for privacy/security reasons.
# NOTE: Fill in these values before running this script.

...

#### Explanation of Changes
1. Cleanup Function:
    - Added a `cleanup_batch_files` function that iterates through all files in the `BATCH_DIR_PATH`.
    - It checks if each file ends with `.npz` (the batch files) and deletes them.

2. Calling Cleanup Function:
    - The `cleanup_batch_files` function is called at the end of the `main` function, ensuring that all batch files are deleted after training and testing are complete.

#### Benefits
- Disk Space Management: Automatically cleaning up batch files ensures that temporary files do not consume unnecessary disk space.

```

- **\*\*Clarity\*\***: Clearly indicates when batch files have been successfully deleted or if there were any issues during the cleanup process.

This modification ensures that your script is more efficient in terms of resource management and keeps your working directory clean.

**Provide an analysis of the following script:**

### Analysis of the Script: `preprocess-release.py`

#### #### Overview

The script `preprocess-release.py` is designed to preprocess trading data from a MySQL database and save it in Parquet format. The preprocessing steps include fetching data in chunks, optimizing data types, normalizing certain columns using MinMaxScaler, writing processed data to Parquet files, and then merging these files into single Parquet files for training and testing datasets.

#### #### Key Components

1. **\*\*Database Connection\*\***:
  - The script uses `pymysql` to connect to a MySQL database.
  - Credentials are stored in the `DB\_CONFIG` dictionary but have been removed for privacy reasons.
2. **\*\*Data Fetching\*\***:
  - Data is fetched in chunks based on `trade\_id`. The range of `trade\_id`s is determined by querying the database.
  - The script splits the data into training and testing sets, with 60% of the data used for training and 40% for testing.
3. **\*\*Data Preprocessing\*\***:
  - Data types are optimized to save memory (e.g., converting `price` and `volume` to `float64`, `side` to `uint8`).
  - The script uses `MinMaxScaler` from `sklearn.preprocessing` to normalize the `price`, `volume`, and `time` columns.
  - A separate scaler is trained on a portion of the training data and saved to a file for later use.
4. **\*\*Parallel Processing\*\***:

- The script employs multiprocessing to handle large datasets efficiently. It uses Python's ``multiprocessing.Pool`` to process chunks of data in parallel, utilizing the specified number of CPU cores.

5. **\*\*Data Writing\*\***:

- Processed data is written to Parquet files using ``pandas.DataFrame.to_parquet``.
- Files are named uniquely based on worker ID and trade range for easy identification.

6. **\*\*Data Merging\*\***:

- After processing, all temporary Parquet files are merged into single Parquet files for training and testing datasets.

7. **\*\*Cleanup\*\***:

- Temporary Parquet files are deleted after the final merge to free up space.

##### Argument Parsing

- The script uses ``argparse`` to handle command-line arguments:
  - ``--table-prefix``: Specifies the prefix of the table name from which data will be fetched.
  - ``--cpu-count``: Specifies the number of CPU cores to use for multiprocessing. Defaults to 4 if not provided.

##### Execution Flow

1. **\*\*Initialization\*\***: Set up directories and initialize necessary components (e.g., scaler).
2. **\*\*Database Connection Setup\*\***: Connect to the MySQL database using the provided configuration.
3. **\*\*Data Range Calculation\*\***: Fetch the minimum and maximum ``trade_id`` from the table.
4. **\*\*Chunking\*\***: Split the data into training and testing sets based on the calculated range.
5. **\*\*Scaler Training\*\***: Train a ``MinMaxScaler`` on a subset of the training data.
6. **\*\*Parallel Data Processing\*\***:
  - Training data is processed in parallel.
  - Testing data is processed in parallel.
7. **\*\*Data Merging\*\***: Merge all temporary Parquet files into final Parquet files for training and testing datasets.
8. **\*\*Cleanup\*\***: Delete temporary Parquet files.

##### Security Considerations

- Database credentials are removed from the script, which is a good practice to prevent exposure of sensitive information.
- The script does not handle other security aspects like SQL injection, but since it constructs queries with static table names and uses parameterized queries where necessary, this risk is minimized.

##### Improvements and Suggestions

1. **\*\*Error Handling\*\***: Add more robust error handling, especially around database connections and file operations.
2. **\*\*Configuration Management\*\***: Consider using a configuration management tool or environment variables to manage sensitive information like database credentials.
3. **\*\*Logging\*\***: Introduce logging instead of print statements for better traceability and debugging.
4. **\*\*Unit Testing\*\***: Write unit tests for individual functions to ensure they work as expected.
5. **\*\*Performance Optimization\*\***: Evaluate performance and optimize queries, data types, and multiprocessing logic if necessary.

This script is well-structured and follows best practices for data preprocessing with Python, making it a solid foundation for further development or integration into larger systems.

**Modify the script such that the starting and ending index for the test dataset is written to a text file**

Certainly! To modify the script so that the starting and ending `trade\_id` indices for the test dataset are written to a text file, you can follow these steps:

1. Define a function to write the indices to a text file.
2. Call this function after determining the indices for the test dataset.

Here's the modified script with the necessary changes:

```
```python
# preprocess-release.py
# Code development was assisted by an LLM (Qwen2.5-coder:32b). Check q32b-log for prompts and responses.
# NOTE: MySQL database credentials have been removed for privacy/security reasons. Fill in these values before running this script.

```

### ### Key Changes

#### 1. **\*\*Function to Write Indices\*\*:**

- A new function `write\_test\_indices\_to\_file` is added to write the starting and ending `trade\_id` indices for the test dataset to a file named `test\_indices.txt`.

#### 2. **\*\*Calling the Function\*\*:**

- The function `write\_test\_indices\_to\_file(training\_end\_trade\_id + 1, end\_trade\_id)` is called after processing both training and testing data to ensure the indices are written before merging the Parquet files.

#### 3. **\*\*Argument Parsing Default Value\*\*:**

- The default value for `--cpu-count` is set to 4 in the argument parser to match the previous behavior.

This modification ensures that the starting and ending `trade\_id` indices for the test dataset are recorded in a text file, making it easier to track and verify the data ranges used for testing.

**Provide analysis of following script:**

```
```python

### Analysis of `lstm_release.py`
```

This script is designed to train and evaluate an LSTM (Long Short-Term Memory) model using financial data, specifically focusing on price predictions. Here's a detailed breakdown of the script:

#### #### Key Components

##### 1. **\*\*Imports:\*\***

- The script imports necessary libraries such as ``pandas``, ``numpy``, ``tensorflow.keras`` for building and training the LSTM model, ``sklearn.metrics`` for evaluating the model, and others like ``os``, ``joblib``, and ``argparse`` for file handling and command-line arguments.

##### 2. **\*\*Constants:\*\***

- File paths for training and testing data (``TRAINING_FILE_PATH``, ``TESTING_FILE_PATH``).
- Directory path for intermediate batch files (``BATCH_DIR_PATH``), output predictions file path (``PREDICTIONS_FILE_PATH``), scaler file path (``SCALER_FILE_PATH``), and test indices file path (``INDICES_FILE_PATH``).

##### 3. **\*\*Utility Functions:\*\***

- ``load_test_indices``: Loads the start and end indices from a file.
- ``load_data``: Loads preprocessed data from a Parquet file and checks for NaN values.
- ``create_sequences_in_batches``: Creates sequences of data for LSTM training and testing in batches, saving them immediately to disk.
- ``load_batches``: Loads batches of sequences from disk with memory constraints.
- ``load_scaler``: Loads the MinMaxScaler used for normalizing data.
- ``get_db_connection``: Establishes a connection to a MySQL database using provided configuration.

##### 4. **\*\*Main Function (`main`):\*\***

- Connects to the database using provided credentials.
- Loads and checks training and testing datasets.
- Loads the MinMaxScaler.
- Normalizes the data.
- Creates sequences of data in batches for both training and testing.
- Builds, compiles, and trains the LSTM model.
- Evaluates the model on test data, calculating performance metrics like Mean Squared Error (MSE) and Mean Absolute Error (MAE).
- Loads actual timestamps from the database.
- Saves predictions to a DataFrame and then inserts them into a new table in the database.
- Saves predictions to a CSV file for debugging purposes.

##### 5. **\*\*Model Architecture:\*\***

- The LSTM model consists of two LSTM layers with dropout layers to prevent overfitting, followed by a dense layer that outputs a single value (predicted price).

- It is compiled using the Adam optimizer and mean squared error as the loss function.

#### 6. **Batch Processing:**

- Data sequences are created in batches to manage memory usage effectively.
- Batches of data are loaded from disk for training and evaluation, ensuring that only a limited number of batches are held in memory at any time.

#### 7. **Evaluation and Saving Results:**

- The script calculates performance metrics on the test set.
- Predictions are saved into both a CSV file and a new table in the MySQL database, with actual timestamps and side information preserved.

#### 8. **Cleanup:**

- Batch files generated during sequence creation are deleted after use to free up disk space.

#### 9. **Command-Line Argument Parsing:**

- The script uses `argparse` to accept command-line arguments for specifying the table prefix, which helps in handling different datasets.

#### #### Points of Consideration

- **Security:** Database credentials and other sensitive information should be stored securely, possibly using environment variables or a secure vault.
- **Error Handling:** While there are checks for NaN values and file existence, additional error handling could be added to improve robustness.
- **Performance Optimization:** The script could benefit from parallel processing during data loading and model training to speed up execution.
- **Scalability:** Considerations should be made for scaling the model with larger datasets or more complex architectures.

#### #### Conclusion

The script is well-structured and provides a comprehensive workflow for training and evaluating an LSTM model on financial data. It handles data preprocessing, model building, training, evaluation, and result saving effectively. However, improvements in error handling, performance optimization, and scalability could further enhance its functionality.

#### **The following error occurs at line 262: "ValueError: All arrays must be of the same length"**

The error message "ValueError: All arrays must be of the same length" indicates that there is a mismatch in the lengths of the arrays being used to create a DataFrame. This typically happens when you are trying to combine arrays or lists of different sizes into a single DataFrame.

Let's focus on the relevant part of the code around line 262:

```
```python
# Save predictions to a dataframe
results_df = pd.DataFrame({
    'predicted_price': y_pred_inv_full[:, 0],
```

```

'volume': y_test_inv_full[:, 1],
'time': time_column, # Use actual timestamps
'side': side_test_inv.astype(int).flatten() # Convert side to int
})

# Save dataframe to the database
predict_table = table_prefix + "_TICK_DATA_predict"
with connection.cursor() as cursor:
    try:
        results_df = results_df.replace(np.nan, None)
        results_val = list(results_df.iteruples(index=False, name=None))

        results_query = f"CREATE TABLE IF NOT EXISTS {predict_table} (trade_id INT AUTO
INCREMENT, price FLOAT, volume FLOAT, time DOUBLE PRECISION(19,8), side
VARCHAR(255))"
        cursor.execute(results_query)
        connection.commit()

        results_query = f"ALTER TABLE {predict_table} AUTO_INCREMENT={start_index}"
        cursor.execute(results_query)
        connection.commit()

        results_query = f"INSERT INTO {predict_table} VALUES (%s, %s, %s, %s)"
        cursor.executemany(results_query, results_val)
        connection.commit()
    except Exception as e:
        print(f"An error occurred inserting data into the database: {e}")
        sys.exit()

# DEBUG: Save predictions to a CSV file
results_df.to_csv(table_prefix + "_" + PREDICTIONS_FILE_PATH, index=False)
print(f"Predictions saved to {table_prefix + "_" + PREDICTIONS_FILE_PATH}")
'''

```

### ### Potential Causes and Solutions

1. **\*\*Mismatch in Lengths of `y\_pred\_inv\_full`, `y\_test\_inv\_full`, `time\_column`, and `side\_test\_inv`:\*\***
  - Ensure that all arrays have the same length before creating the DataFrame.
2. **\*\*Check Lengths Before Creating DataFrame:\*\***
  - Add print statements to check the lengths of each array before creating the DataFrame.

### ### Debugging Steps

1. **\*\*Print Lengths of Arrays:\*\***

```

python
print(f"Length of y_pred_inv_full[:, 0]: {len(y_pred_inv_full[:, 0])}")
print(f"Length of y_test_inv_full[:, 1]: {len(y_test_inv_full[:, 1])}")

```

```
print(f"Length of time_column: {len(time_column)}")
print(f"Length of side_test_inv.flatten(): {len(side_test_inv.flatten())}")
```

```

## 2. **\*\*Ensure Consistent Indices:\*\***

- Ensure that the indices used to extract `side\_values` and `time\_values` are consistent with the lengths of the other arrays.

### ### Example Debugging Code

Add the following debugging code before creating the DataFrame:

```
```python
# Check lengths of arrays
print(f"Length of y_pred_inv_full[:, 0]: {len(y_pred_inv_full[:, 0])}")
print(f"Length of y_test_inv_full[:, 1]: {len(y_test_inv_full[:, 1])}")
print(f"Length of time_column: {len(time_column)}")
print(f"Length of side_test_inv.flatten(): {len(side_test_inv.flatten())}")

# Ensure consistency in indices
assert len(y_pred_inv_full[:, 0]) == len(y_test_inv_full[:, 1]), "Mismatch in lengths of y_pred_inv_full and y_test_inv_full"
assert len(y_pred_inv_full[:, 0]) == len(time_column), "Mismatch in lengths of y_pred_inv_full and time_column"
assert len(y_pred_inv_full[:, 0]) == len(side_test_inv.flatten()), "Mismatch in lengths of y_pred_inv_full and side_test_inv"

# Create the DataFrame
results_df = pd.DataFrame({
    'predicted_price': y_pred_inv_full[:, 0],
    'volume': y_test_inv_full[:, 1],
    'time': time_column, # Use actual timestamps
    'side': side_test_inv.astype(int).flatten() # Convert side to int
})
```

```

### ### Additional Checks

#### 1. **\*\*Check Lengths During Batch Processing:\*\***

- Ensure that the lengths of `X\_batches\_chunk`, `y\_batches\_chunk`, and other relevant arrays are consistent during batch processing.

#### 2. **\*\*Validate Indices Extraction:\*\***

- Verify that the indices used to extract `side\_values` and `time\_values` from `testing\_data` are correct and match the expected lengths.

### ### Example Check During Batch Processing

Add checks in the loop where `side\_test\_all` and `time\_test\_all` are populated:

```

```python
for X_test_batches, y_test_batches in load_batches('test'):
    for i, (X_test_batch, y_test_batch) in enumerate(zip(X_test_batches, y_test_batches)):
        print(f'Evaluating batch {i + 1}/{len(X_test_batches)}")
        y_pred = model.predict(X_test_batch)
        y_pred_all.extend(y_pred.flatten())
        y_test_all.extend(y_test_batch)

    # Extract side and time values from the testing data
    start_idx = seq_length - 1 + i * batch_size
    end_idx = min(start_idx + len(y_test_batch), len(testing_data) - 1)
    print(f'Start index: {start_idx}, End index: {end_idx}")
    side_values = testing_data['side'].iloc[start_idx:end_idx].values
    time_values = testing_data['time'].iloc[start_idx:end_idx].values

    # Ensure lengths match
    assert len(side_values) == len(y_test_batch), f"Mismatch in lengths of side_values and
y_test_batch at batch {i + 1}"
    assert len(time_values) == len(y_test_batch), f"Mismatch in lengths of time_values and
y_test_batch at batch {i + 1}"

    side_test_all.extend(side_values)
    time_test_all.extend(time_values)
...

```

By adding these checks, you can identify where the mismatch is occurring and ensure that all arrays have consistent lengths before creating the DataFrame.
